# What is AWS Key Management Service?

AWS Key Management Service (AWS KMS) is a managed service that makes it easy for you to create and control the encryption keys used to encrypt your data. The customer master keys that you create in AWS KMS are protected by hardware security modules (HSMs). Our HSMs are validated by the [FIPS 140-2 Cryptographic Module Validation Program](#) except in the China (Beijing) and China (Ningxia) Regions.

AWS KMS is integrated with most [other AWS services](#) that encrypt your data with encryption keys that you manage. AWS KMS is also integrated with [AWS CloudTrail](#) to provide encryption key usage logs to help meet your auditing, regulatory and compliance needs.

You can perform the following management actions on your AWS KMS master keys:

- Create, describe, and list master keys
- Enable and disable master keys
- Create and view grants and access control policies for your master keys
- Enable and disable automatic rotation of the cryptographic material in a master key
- Import cryptographic material into an AWS KMS master key
- Tag your master keys for easier identification, categorizing, and tracking
- Create, delete, list, and update *aliases*, which are friendly names associated with your master keys
- Delete master keys to complete the key lifecycle

With AWS KMS you can also perform the following cryptographic functions using master keys:

- Encrypt, decrypt, and re-encrypt data
- Generate data encryption keys that you can export from the service in plaintext or encrypted under a master key that doesn't leave the service
- Generate random numbers suitable for cryptographic applications

By using AWS KMS, you gain more control over access to data you encrypt. You can use the key management and cryptographic features directly in your applications or through AWS services that are integrated with AWS KMS. Whether you are writing applications for AWS or using AWS services, AWS KMS enables you to maintain control over who can use your master keys and gain access to your encrypted data.

AWS KMS is integrated with AWS CloudTrail, a service that delivers log files to an Amazon S3 bucket that you designate. By using CloudTrail you can monitor and investigate how and when your master keys have been used and by whom.

## Learn More

- For a more detailed introduction to AWS KMS, see [AWS KMS Concepts \(p. 2\)](#).
- For information about the AWS KMS API, see the [AWS Key Management Service API Reference](#).

- For detailed technical information about how AWS KMS uses cryptography and secures master keys, see the [AWS Key Management Service Cryptographic Details](#) whitepaper. This whitepaper does not describe how AWS KMS works in the China (Beijing) and China (Ningxia) Regions.
- For help with questions about AWS KMS, see the [AWS Key Management Service Discussion Forum](#).

### AWS KMS in AWS Regions

The AWS Regions in which AWS KMS is supported are listed in [AWS Key Management Service Endpoints and Quotas](#). If an AWS KMS feature is not supported in an AWS Region that AWS KMS supports, the regional difference is described in the topic about the feature.

### AWS KMS Pricing

As with other AWS products, there are no contracts or minimum commitments for using AWS KMS. For more information about AWS KMS pricing, see [AWS Key Management Service Pricing](#).

### Service Level Agreement

AWS Key Management Service is backed by a [service level agreement](#) that defines our service availability policy.

## AWS Key Management Service Concepts

Learn the basic terms and concepts in AWS Key Management Service (AWS KMS) and how they work together to help protect your data.

## Customer Master Keys (CMKs)

Customer master keys are the primary resources in AWS KMS.

A *customer master key* (CMK) is a logical representation of a master key. The CMK includes metadata, such as the key ID, creation date, description, and key state. The CMK also contains the key material used to encrypt and decrypt data.

AWS KMS supports symmetric and asymmetric CMKs. A *symmetric CMK* represents a 256-bit key that is used for encryption and decryption. An *asymmetric CMK* represents an RSA key pair that is used for

encryption and decryption or signing and verification (but not both), or an elliptic curve (ECC) key pair that is used for signing and verification. For detailed information about symmetric and asymmetric CMKs, see [Using Symmetric and Asymmetric Keys \(p. 129\)](#).

CMKs are created in AWS KMS. Symmetric CMKs and the private keys of asymmetric CMKs never leave AWS KMS unencrypted. To manage your CMK, you can use the AWS Management Console or the [AWS KMS API](#). To use a CMK in cryptographic operations, you must use the AWS KMS API. This strategy differs from [data keys \(p. 4\)](#). AWS KMS does not store, manage, or track your data keys. You must use them outside of AWS KMS.

By default, AWS KMS creates the key material for a CMK. You cannot extract, export, view, or manage this key material. Also, you cannot delete this key material; you must [delete the CMK \(p. 160\)](#). However, you can [import your own key material \(p. 147\)](#) into a CMK or create the key material for a CMK in the AWS CloudHSM cluster associated with an [AWS KMS custom key store \(p. 172\)](#).

For information about creating and managing CMKs, see [Getting Started \(p. 17\)](#). For information about using CMKs, see the [AWS Key Management Service API Reference](#).

There are three types of CMKs in AWS accounts: customer managed CMKs, AWS managed CMKs, and AWS owned CMKs.

Type of CMK	Can View CMK Metadata	Can Manage CMK	Used Only for My AWS Account	
<a href="#">Customer managed CMK (p. 3)</a>	Yes	Yes	Yes	
<a href="#">AWS managed CMK (p. 4)</a>	Yes	No	Yes	
<a href="#">AWS owned CMK (p. 4)</a>	No	No	No	

To distinguish customer managed CMKs from AWS managed CMKs, use the `KeyManager` field in the [DescribeKey](#) operation response. For customer managed CMKs, the `KeyManager` value is `Customer`. For AWS managed CMKs, the `KeyManager` value is `AWS`.

[AWS services that integrate with AWS KMS \(p. 228\)](#) differ in their support for CMKs. Some AWS services encrypt your data by default with an AWS owned CMK or an AWS managed CMK. Other AWS services offer to encrypt your data under a customer managed CMK that you choose. And other AWS services support all types of CMKs to allow you the ease of an AWS owned CMK, the visibility of an AWS managed CMK, or the control of a customer managed CMK.

## Customer Managed CMKs

*Customer managed CMKs* are CMKs in your AWS account that you create, own, and manage. You have full control over these CMKs, including establishing and maintaining their [key policies, IAM policies, and grants \(p. 46\)](#), [enabling and disabling \(p. 41\)](#) them, [rotating their cryptographic material \(p. 142\)](#), [adding tags \(p. 39\)](#), [creating aliases \(p. 344\)](#) that refer to the CMK, and [scheduling the CMKs for deletion \(p. 160\)](#).

Customer managed CMKs appear on the **Customer managed keys** page of the AWS Management Console for AWS KMS. To definitively identify a customer managed CMK, use the [DescribeKey](#) operation. For customer managed CMKs, the value of the `KeyManager` field of the `DescribeKey` response is `CUSTOMER`.

You can use your customer managed CMKs in cryptographic operations and audit their use in AWS CloudTrail logs. In addition, many [AWS services that integrate with AWS KMS \(p. 228\)](#) let you specify a customer managed CMK to protect the data that they store and manage for you.

Customer managed CMKs incur a monthly fee and a fee for use in excess of the free tier. They are counted against the AWS KMS [limits \(p. 353\)](#) for your account. For details, see [AWS Key Management Service Pricing](#) and [Quotas \(p. 353\)](#).

## AWS Managed CMKs

*AWS managed CMKs* are CMKs in your account that are created, managed, and used on your behalf by an AWS service that is integrated with AWS KMS.

You can [view the AWS managed CMKs \(p. 22\)](#) in your account, [view their key policies \(p. 61\)](#), and [audit their use \(p. 293\)](#) in AWS CloudTrail logs. However, you cannot manage these CMKs or change their key policies. And, you cannot use AWS managed CMKs in cryptographic operations directly; the service that creates them uses them on your behalf.

AWS managed CMKs appear on the **AWS managed keys** page of the AWS Management Console for AWS KMS. You can also identify most AWS managed CMKs by their aliases, which have the format `aws/service-name`, such as `aws/redshift`. To definitively identify an AWS managed CMK, use the [DescribeKey](#) operation. For AWS managed CMKs, the value of the `KeyManager` field of the `DescribeKey` response is `AWS`.

You do not pay a monthly fee for AWS managed CMKs. They can be subject to fees for use in excess of the free tier, but some AWS services cover these costs for you. For details, see the encryption section of the service documentation. AWS managed CMKs do not count against limits on the number of CMKs in each Region of your account. But when they are used on behalf of a principal in your account, these CMKs count against request rate limits. For details, see [AWS Key Management Service Pricing](#) and [Quotas \(p. 353\)](#).

## AWS Owned CMKs

*AWS owned CMKs* are not in your AWS account. They are part of a collection of CMKs that AWS owns and manages for use in multiple AWS accounts. AWS services can use AWS owned CMKs to protect your data.

You cannot view, manage, or use AWS owned CMKs, or audit their use. However, you do not need to do any work or change any programs to protect the keys that encrypt your data.

You are not charged a monthly fee or a usage fee for use of AWS owned CMKs and they do not count against AWS KMS limits for your account.

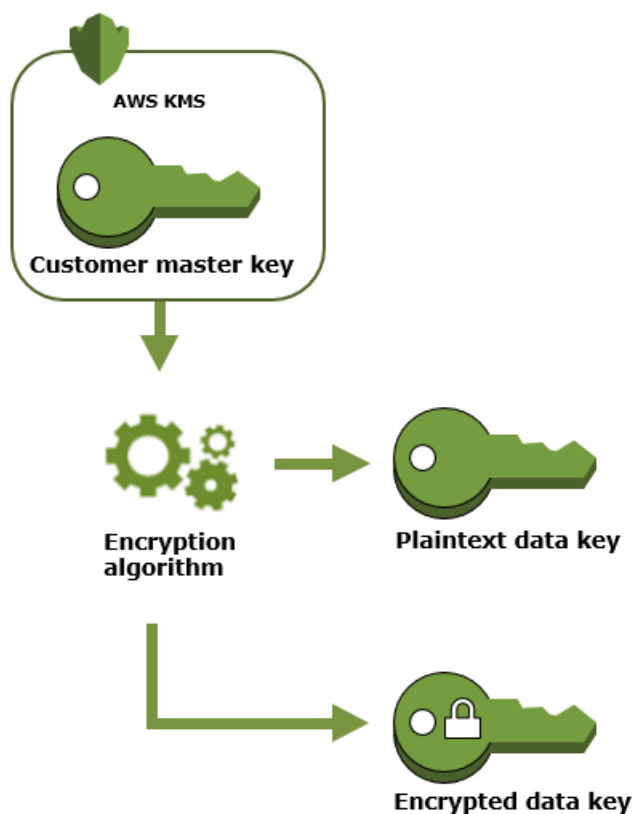

## Data Keys

*Data keys* are encryption keys that you can use to encrypt data, including large amounts of data and other data encryption keys.

You can use AWS KMS [customer master keys \(p. 2\)](#) (CMKs) to generate, encrypt, and decrypt data keys. However, AWS KMS does not store, manage, or track your data keys, or perform cryptographic operations with data keys. You must use and manage data keys outside of AWS KMS.

## Create a Data Key

To create a data key, call the [GenerateDataKey](#) operation. AWS KMS uses the CMK that you specify to generate a data key. The operation returns a plaintext copy of the data key and a copy of the data key encrypted under the CMK. The following image shows this operation.

AWS KMS also supports the [GenerateDataKeyWithoutPlaintext](#) operation, which returns only an encrypted data key. When you need to use the data key, ask AWS KMS to [decrypt](#) it.

## Encrypt Data with a Data Key

AWS KMS cannot use a data key to encrypt data. But you can use the data key outside of KMS, such as by using OpenSSL or a cryptographic library like the [AWS Encryption SDK](#).

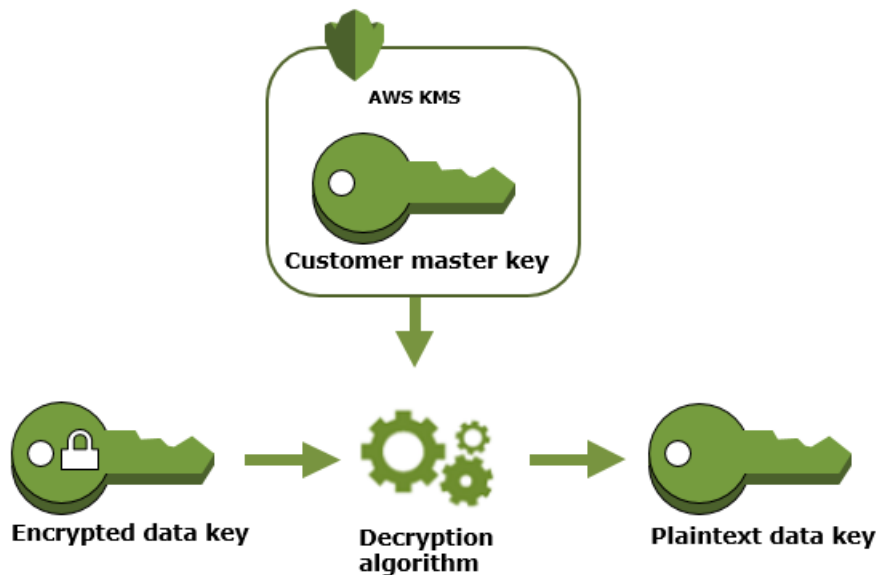

After using the plaintext data key to encrypt data, remove it from memory as soon as possible. You can safely store the encrypted data key with the encrypted data so it is available to decrypt the data.

## Decrypt Data with a Data Key

To decrypt your data, pass the encrypted data key to the [Decrypt](#) operation. AWS KMS uses your CMK to decrypt the data key and then it returns the plaintext data key. Use the plaintext data key to decrypt your data and then remove the plaintext data key from memory as soon as possible.

The following diagram shows how to use the `Decrypt` operation to decrypt an encrypted data key.

## Data Key Pairs

*Data key pairs* are asymmetric data keys that consist of a mathematically-related public key and private key. They are designed to be used for client-side encryption and decryption or signing and verification outside of AWS KMS.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

Unlike the data key pairs that tools like OpenSSL generate, AWS KMS protects the private key in each data key pair under a symmetric CMK in AWS KMS that you specify. However, AWS KMS does not store, manage, or track your data key pairs, or perform cryptographic operations with data key pairs. You must use and manage data key pairs outside of AWS KMS.

AWS KMS supports the following types of data key pairs:

- RSA key pairs: RSA\_2048, RSA\_3072, and RSA\_4096
- Elliptic curve key pairs, ECC\_NIST\_P256, ECC\_NIST\_P384, ECC\_NIST\_P521, and ECC\_SECG\_P256K1

The type of data key pair that you select usually depends on your use case or regulatory requirements. Most certificates require RSA keys. Elliptic curve keys are often used for digital signatures. ECC\_SECG\_P256K1 keys are commonly used for cryptocurrencies.

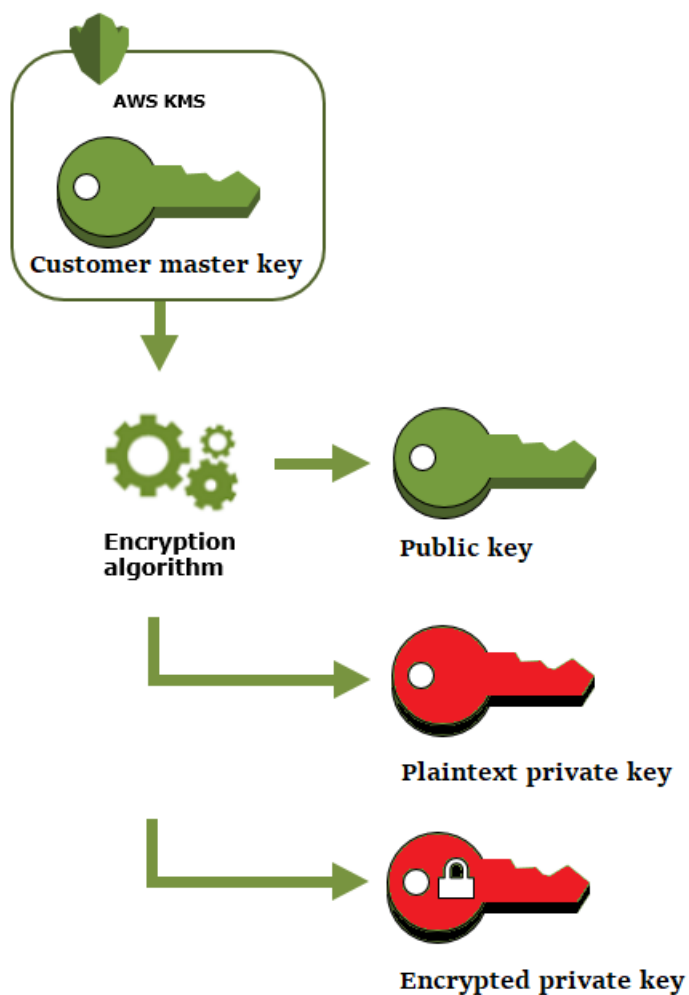

## Create a Data Key Pair

To create a data key pair, call the [GenerateDataKeyPair](#) or [GenerateDataKeyPairWithoutPlaintext](#) operations. Specify the symmetric CMK you want to use to encrypt the private key.

`GenerateDataKeyPair` returns a plaintext public key, a plaintext private key, and an encrypted private key. Use this operation when you need a plaintext private key immediately, such as to generate a digital signature.

`GenerateDataKeyPairWithoutPlaintext` returns a plaintext public key and an encrypted private key, but not a plaintext private key. Use this operation when you don't need a plaintext private key immediately, such as when you're encrypting with a public key. Later, when you need a plaintext private key to decrypt the data, you can call the [Decrypt](#) operation.

The following image shows the `GenerateDataKeyPair` operation. The `GenerateDataKeyWithoutPlaintext` operation omits the plaintext private key.

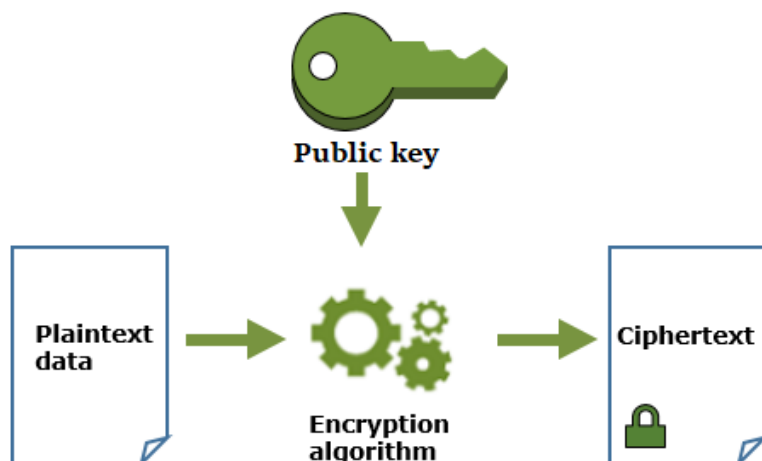

## Encrypt Data with a Data Key Pair

When you encrypt with a data key pair, you use the public key of the pair to encrypt the data and the private key of the same pair to decrypt the data. Typically, data key pairs are used when many parties need to encrypt data that only the party that holds the private key can decrypt.

The parties with the public key use that key to encrypt data, as shown in the following diagram.

## Decrypt Data with a Data Key Pair

To decrypt your data, use the private key in the data key pair. For the operation to succeed, the public and private keys must be from the same data key pair, and you must use the same encryption algorithm.

To decrypt the encrypted private key, pass it to the [Decrypt](#) operation. Use the plaintext private key to decrypt the data. Then remove the plaintext private key from memory as soon as possible.

The following diagram shows how to use the private key in a data key pair to decrypt ciphertext.

## Sign Messages with a Data Key Pair

To generate a cryptographic signature for a message, use the private key in the data key pair. Anyone with the public key can use it to verify that the message was signed with your private key and that it has not changed since it was signed.

If your private key is encrypted, pass the encrypted private key to the [Decrypt](#) operation. AWS KMS uses your CMK to decrypt the data key and then it returns the plaintext private key. Use the plaintext private key to generate the signature. Then remove the plaintext private key from memory as soon as possible.

To sign a message, create a message digest using a cryptographic hash function, such as the [dgst](#) command in OpenSSL. Then, pass your plaintext private key to the signing algorithm. The result is a signature that represents the contents of the message.

The following diagram shows how to use the private key in a data key pair to sign a message.

## Verify a Signature with a Data Key Pair

Anyone who has the public key in your data key pair can use it to verify the signature that you generated with your private key. Verification confirms that an authorized user signed the message with the specified private key and signing algorithm, and the message hasn't changed since it was signed.

To be successful, the party verifying the signature must generate the same type of digest, use the same algorithm, and use the public key that corresponds to the private key used to sign the message.

The following diagram shows how to use the public key in a data key pair to verify a message signature.

## Key Spec

The *key spec* is a CMK property that represents cryptographic configuration of the CMK. The key spec determines whether the CMK is symmetric or asymmetric, the type of key material in the CMK, and the encryption algorithms or signing algorithms you can use with the CMK.

Typically, the key spec that you choose for your CMK is based on your use case and regulatory requirements. You choose the key spec when you [create the CMK \(p. 17\)](#), and you cannot change it. If you've chosen the wrong key spec, [delete the CMK \(p. 160\)](#), and create a new one.

For a list of key specs and help with choosing a key spec, see [Selecting the Key Spec \(p. 133\)](#). To find the key spec of a CMK, use the [DescribeKey](#) operation, or see the **Cryptographic configuration** section of the detail page for a CMK in the AWS KMS console. For help, see [Viewing Keys \(p. 22\)](#).

### Note

In AWS KMS API operations, the key spec for CMKs is known as the `CustomerMasterKeySpec`. This distinguishes it from the key spec for data keys (`KeySpec`) and data key pairs (`KeyPairSpec`), and the key spec used when wrapping key material for import (`WrappingKeySpec`). Each key spec type has different values.

To limit the key specs that principals can use when creating CMKs, use the [kms:CustomerMasterKeySpec](#) (p. 91) condition key. You can also use the `kms:CustomerMasterKeySpec` condition key to allow principals to call AWS KMS operations for a CMK based on its key spec. For example, you can deny permission to schedule deletion of CMK with an `RSA_4096` key spec.

## Key Usage

*Key usage* is a CMK property that determines whether a CMK is used for encryption and decryption -or- signing and verification. You cannot choose both. Using a CMK for more than one type of operations makes the product of both operations more vulnerable to attack.

The key usage for symmetric CMKs is always encryption and decryption. The key usage for elliptic curve (ECC) CMKs is always signing and verification. You only need to choose a key usage for RSA CMKs. You choose the key usage when you [create the CMK](#) (p. 17), and you cannot change it. If you've chosen the wrong key usage, [delete the CMK](#) (p. 160), and create a new one.

For choosing the key usage, see [Selecting the Key Usage](#) (p. 132). To find the key usage of a CMK, use the [DescribeKey](#) operation, or see the **Cryptographic configuration** section of the detail page for a CMK in the AWS KMS console. For help, see [Viewing Keys](#) (p. 22).

To allow principals to create CMKs only for signing and verification or only for encryption and decryption, use the [kms:CustomerMasterKeyUsage](#) (p. 92) condition key. You can also use the `kms:CustomerMasterKeyUsage` condition key to allow principals to call API operations for a CMK based on its key usage. For example, you can allow permission to disable a CMK only if its key usage is `SIGN_VERIFY`.

## Envelope Encryption

When you encrypt your data, your data is protected, but you have to protect your encryption key. One strategy is to encrypt it. *Envelope encryption* is the practice of encrypting plaintext data with a data key, and then encrypting the data key under another key.

You can even encrypt the data encryption key under another encryption key, and encrypt that encryption key under another encryption key. But, eventually, one key must remain in plaintext so you can decrypt the keys and your data. This top-level plaintext key encryption key is known as the *master key*.

AWS KMS helps you to protect your master keys by storing and managing them securely. Master keys stored in AWS KMS, known as [customer master keys](#) (p. 2) (CMKs), never leave the AWS KMS [FIPS validated hardware security modules](#) unencrypted. To use an AWS KMS CMK, you must call AWS KMS.

Envelope encryption offers several benefits:

- **Protecting data keys**

When you encrypt a data key, you don't have to worry about storing the encrypted data key, because the data key is inherently protected by encryption. You can safely store the encrypted data key alongside the encrypted data.

- **Encrypting the same data under multiple master keys**

Encryption operations can be time consuming, particularly when the data being encrypted are large objects. Instead of re-encrypting raw data multiple times with different keys, you can re-encrypt only the data keys that protect the raw data.

- **Combining the strengths of multiple algorithms**

In general, symmetric key algorithms are faster and produce smaller ciphertexts than public key algorithms. But public key algorithms provide inherent separation of roles and easier key management. Envelope encryption lets you combine the strengths of each strategy.

## Encryption Context

All AWS KMS cryptographic operations ([Encrypt](#), [Decrypt](#), [ReEncrypt](#), [GenerateDataKey](#), and [GenerateDataKeyWithoutPlaintext](#)) that use symmetric CMKs accept an *encryption context*, an optional set of key-value pairs that can contain additional contextual information about the data. AWS KMS uses the encryption context as [additional authenticated data](#) (AAD) to support [authenticated encryption](#).

You cannot specify an encryption context in a cryptographic operation with an [asymmetric CMK](#) (p. 130). The standard asymmetric encryption algorithms that AWS KMS uses do not support an encryption context.

When you include an encryption context in an encryption request, it is cryptographically bound to the ciphertext such that the same encryption context is required to decrypt (or decrypt and re-encrypt) the data. If the encryption context provided in the decryption request is not an exact, case-sensitive match, the decrypt request fails. Only the order of the key-value pairs in the encryption context can vary.

The encryption context is not secret. It appears in plaintext in [AWS CloudTrail Logs](#) (p. 293) so you can use it to identify and categorize your cryptographic operations.

An encryption context can consist of any keys and values. However, because it is not secret and not encrypted, your encryption context should not include sensitive information. We recommend that your encryption context describe the data being encrypted or decrypted. For example, when you encrypt a file, you might use part of the file path as encryption context.

The key and value in an encryption context pair must be simple literal strings. They cannot be integers or objects, or any type that is not fully resolved. If you use a different type, such as an integer or float, AWS KMS interprets it as a string.

```
"encryptionContext": {  
  "department": "10103.0"  
}
```

The encryption context key and value can include special characters, such as underscores (\_), dashes (-), slashes (/), and colons (:).

For example, [Amazon Simple Storage Service \(p. 266\)](#) (Amazon S3) uses an encryption context in which the key is `aws:s3:arn`. The value is the S3 bucket path to the file that is being encrypted.

```
"encryptionContext": {  
  "aws:s3:arn": "arn:aws:s3:::bucket_name/file_name"  
}
```

You can also use the encryption context to refine or limit access to customer master keys (CMKs) in your account. You can use the encryption context [as a constraint in grants \(p. 115\)](#) and as a [condition in policy statements \(p. 86\)](#).

To learn how to use encryption context to protect the integrity of encrypted data, see the post [How to Protect the Integrity of Your Encrypted Data by Using AWS Key Management Service and EncryptionContext](#) on the AWS Security Blog.

More about encryption context.

## Encryption Context in Policies

The encryption context is used primarily to verify integrity and authenticity. But you can also use the encryption context to control access to symmetric customer master keys (CMKs) in key policies and IAM policies.

The `kms:EncryptionContext` (p. 96) and `kms:EncryptionContextKeys` (p. 96) condition keys allow (or deny) a permission only when the request includes particular encryption context keys or key-value pairs.

For example, the following key policy statement allows the `RoleForExampleApp` role to use the CMK in Decrypt operations. It uses the `kms:EncryptionContext` condition key to allow this permission only when the encryption context in the request includes an `AppName:ExampleApp` encryption context pair.

```
{  
  "Effect": "Allow",  
  "Principal": {  
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"  
  },  
  "Action": "kms:Decrypt",  
  "Resource": "*",  
  "Condition": {  
    "ForAnyValue:StringEquals": {  
      "kms:EncryptionContext:AppName": "ExampleApp"  
    }  
  }  
}
```

For more information about these encryption context condition keys, see [Using Policy Conditions with AWS KMS \(p. 86\)](#).

## Encryption Context in Grants

When you [create a grant \(p. 115\)](#), you can include [grant constraints](#) that allow access only when a request includes a particular encryption context or encryption context keys. For details about the `EncryptionContextEquals` and `EncryptionContextSubset` grant constraints, see [Grant Constraints \(p. 116\)](#).

To specify an encryption context constraint in a grant for a symmetric CMK, use the `Constraints` parameter in the [CreateGrant](#) operation. This example uses the AWS Command Line Interface, but you can use any AWS SDK. The grant that this command creates gives the `exampleUser` permission to call the [Decrypt](#) operation. But that permission is effective only when the encryption context in the Decrypt request includes a `"Department": "IT"` encryption context pair.

```
$ aws kms create-grant \  
  --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \  
  --grantee-principal arn:aws:iam::111122223333:user/exampleUser \  
  --operations Decrypt \  
  --retiring-principal arn:aws:iam::111122223333:role/adminRole \  
  --constraints EncryptionContextSubset={Department=IT}
```

The resulting grant looks like the following one. Notice that the permission granted to `exampleUser` is effective only when the Decrypt request includes the encryption context pair specified in the grant constraint. To find the grants on a CMK, use the [ListGrants](#) operation.

```
$ aws kms list-grants --key-id 1234abcd-12ab-34cd-56ef-1234567890ab  
  
{  
  "Grants": [  
    {  
      "Name": "",  
      "IssuingAccount": "arn:aws:iam::111122223333:root",  
      "GrantId": "8c94d1f12f5e69f440bae30eaec9570bb1fb7358824f9ddfa1aa5a0dab1a59b2",  
      "Operations": [  
        "Decrypt"  
      ],  
      "GranteePrincipal": "arn:aws:iam::111122223333:user/exampleUser",  
      "Constraints": {  
        "EncryptionContextSubset": {  
          "Department": "IT"  
        }  
      },  
      "CreationDate": 1568565290.0,  
      "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",  
      "RetiringPrincipal": "arn:aws:iam::111122223333:role/adminRole"  
    }  
  ]  
}
```

AWS services often use encryption context constraints in the grants that give them permission to use CMKs in your AWS account. For example, Amazon DynamoDB uses a grant like the following one to get permission to use the [AWS managed CMK \(p. 4\)](#) for DynamoDB in your account. The `EncryptionContextSubset` grant constraint in this grant makes the permissions in the grant effective only when the encryption context in the request includes `"subscriberID": "111122223333"` and `"tableName": "Services"` pairs. This grant constraint means that the grant allows DynamoDB to use the specified CMK only for a particular table in your AWS account.

To get this output, run the [ListGrants](#) operation on the AWS managed CMK for DynamoDB in your account.

```
$ aws kms list-grants --key-id 0987dcba-09fe-87dc-65ba-ab0987654321

{
  "Grants": [
    {
      "Operations": [
        "Decrypt",
        "Encrypt",
        "GenerateDataKey",
        "ReEncryptFrom",
        "ReEncryptTo",
        "RetireGrant",
        "DescribeKey"
      ],
      "IssuingAccount": "arn:aws:iam::111122223333:root",
      "Constraints": {
        "EncryptionContextSubset": {
          "aws:dynamodb:tableName": "Services",
          "aws:dynamodb:subscriberId": "111122223333"
        }
      },
      "CreationDate": 1518567315.0,
      "KeyId": "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321",
      "GranteePrincipal": "dynamodb.us-west-2.amazonaws.com",
      "RetiringPrincipal": "dynamodb.us-west-2.amazonaws.com",
      "Name": "8276b9a6-6cf0-46f1-b2f0-7993a7f8c89a",
      "GrantId": "1667b97d27cf748cf05b487217dd4179526c949d14fb3903858e25193253fe59"
    }
  ]
}
```

## Logging Encryption Context

AWS KMS uses AWS CloudTrail to log the encryption context so you can determine which CMKs and data have been accessed. The log entry shows exactly which CMK was used to encrypt or decrypt specific data referenced by the encryption context in the log entry.

### Important

Because the encryption context is logged, it must not contain sensitive information.

## Storing Encryption Context

To simplify use of any encryption context when you call the [Decrypt](#) or [ReEncrypt](#) operations, you can store the encryption context alongside the encrypted data. We recommend that you store only enough of the encryption context to help you create the full encryption context when you need it for encryption or decryption.

For example, if the encryption context is the fully qualified path to a file, store only part of that path with the encrypted file contents. Then, when you need the full encryption context, reconstruct it from the stored fragment. If someone tampers with the file, such as renaming it or moving it to a different location, the encryption context value changes and the decryption request fails.

## Key Policies

When you create a CMK, you determine who can use and manage that CMK. These permissions are contained in a document called the *key policy*. You can use the key policy to add, remove, or change permissions at any time for a customer managed CMK. But you cannot edit the key policy for an AWS managed CMK. For more information, see [Authentication and Access Control for AWS KMS](#) (p. 46).

## Grants

A *grant* is another mechanism for providing permissions. It's an alternative to key policies. Because grants can be very specific, and are easy to create and revoke, they are often used to provide temporary permissions or more granular permissions.

## Grant Tokens

When you create a grant, the permissions specified in the grant might not take effect immediately due to [eventual consistency](#). If you need to mitigate the potential delay, use the *grant token* that you receive in the response to your [CreateGrant](#) request. You can pass the grant token with some AWS KMS API requests to make the permissions in the grant take effect immediately. The following AWS KMS API operations accept grant tokens:

- [CreateGrant](#)
- [Decrypt](#)
- [DescribeKey](#)
- [Encrypt](#)
- [GenerateDataKey](#)
- [GenerateDataKeyWithoutPlaintext](#)
- [ReEncrypt](#)
- [RetireGrant](#)

A grant token is not a secret. The grant token contains information about who the grant is for and therefore who can use it to cause the grant's permissions to take effect more quickly.

## Auditing CMK Usage

You can use AWS CloudTrail to audit key usage. CloudTrail creates log files that contain a history of AWS API calls and related events for your account. These log files include all AWS KMS API requests made with the AWS Management Console, AWS SDKs, and command line tools. The log files also include requests to AWS KMS that AWS services make on your behalf. You can use these log files to find important information, including when the CMK was used, the operation that was requested, the identity of the requester, and the source IP address. For more information, see [Logging AWS KMS API Calls with AWS CloudTrail \(p. 293\)](#) and the [AWS CloudTrail User Guide](#).

## Key Management Infrastructure

A common practice in cryptography is to encrypt and decrypt with a publicly available and peer-reviewed algorithm such as AES (Advanced Encryption Standard) and a secret key. One of the main problems with cryptography is that it's very hard to keep a key secret. This is typically the job of a key management infrastructure (KMI). AWS KMS operates the KMI for you. AWS KMS creates and securely stores your master keys, called CMKs. For more information about how AWS KMS operates, see the [AWS Key Management Service Cryptographic Details](#) whitepaper.

# Getting Started

You can use the [AWS Management Console](#) and [AWS KMS API operations](#) to create, view, edit, tag, enable, disable, topics.

## Topics

- [Creating Keys \(p. 17\)](#)
- [Viewing Keys \(p. 22\)](#)
- [Editing Keys \(p. 36\)](#)
- [Tagging Keys \(p. 39\)](#)
- [Enabling and Disabling Keys \(p. 41\)](#)
- [Downloading Public Keys \(p. 43\)](#)

## Creating Keys

You can create [symmetric and asymmetric customer master keys \(p. 129\)](#) (CMKs) in the AWS Management Console or by using the [CreateKey](#) operation. During this process, you determine the cryptographic configuration of your CMK and the origin of its key material. You cannot change these properties after the CMK is created. You also set the key policy for the CMK, which you can change at any time.

If you are creating a CMK to encrypt data you store or manage in an AWS service, create a symmetric CMK. AWS services that are integrated with AWS KMS do not support asymmetric CMKs. For help deciding which type of CMK to create, see [How to Choose Your CMK Configuration \(p. 131\)](#).

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

## Learn More:

- For help creating a CMK with imported key material, see [Create a Customer Master Key With No Key Material \(p. 150\)](#).
- For help creating a CMK in a custom key store, see [Creating CMKs in a Custom Key Store \(p. 192\)](#).
- For help determining whether an existing CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).
- To use your CMKs programmatically and in command line interface operations, you need a key ID or key ARN. For detailed instructions, see [Finding the Key ID and ARN \(p. 32\)](#).

## Topics

- [Creating Symmetric CMKs \(p. 17\)](#)
- [Creating Asymmetric CMKs \(p. 20\)](#)

## Creating Symmetric CMKs

You can create [symmetric CMKs \(p. 130\)](#) in the AWS Management Console or by using the AWS KMS API. Symmetric key encryption uses the same key to encrypt and decrypt data.

## Creating Symmetric CMKs (Console)

You can use the AWS Management Console to create customer master keys (CMKs).

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose **Create key**.
5. To create a symmetric CMK, for **Key type** choose **Symmetric**.

For information about how to create an asymmetric CMK in the AWS KMS console, see [Creating Asymmetric CMKs \(Console\) \(p. 20\)](#).

6. Choose **Next**.
7. Type an alias for the CMK. The alias name cannot begin with **aws/**. The **aws/** prefix is reserved by Amazon Web Services to represent AWS managed CMKs in your account.

An alias is a display name that you can use to identify the CMK. We recommend that you choose an alias that indicates the type of data you plan to protect or the application you plan to use with the CMK.

Aliases are required when you create a CMK in the AWS Management Console. They are optional when you use the [CreateKey](#) operation.

8. (Optional) Type a description for the CMK.

Enter a description that explains the type of data you plan to protect or the application you plan to use with the CMK. Don't use the description format that's used for [AWS managed CMKs \(p. 4\)](#). The *Default master key that protects my ... when no other key is defined* description format is reserved for AWS managed CMKs.

You can add a description now or update it any time unless the [key state \(p. 223\)](#) is **Pending Deletion**. To add, change, or delete the description of an existing customer managed CMK, [edit the CMK \(p. 36\)](#) in the AWS Management Console or use the [UpdateKeyDescription](#) operation.

9. Choose **Next**.
10. (Optional) Type a tag key and an optional tag value. To add more than one tag to the CMK, choose **Add tag**.

When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. For information about tagging CMKs, see [Tagging Keys \(p. 39\)](#).

11. Choose **Next**.
12. Select the IAM users and roles that can administer the CMK.

### Note

IAM policies can give other IAM users and roles permission to manage the CMK.

13. (Optional) To prevent the selected IAM users and roles from deleting this CMK, in the **Key deletion** section at the bottom of the page, clear the **Allow key administrators to delete this key** check box.
14. Choose **Next**.
15. Select the IAM users and roles that can use the CMK for cryptographic operations.

### Note

The AWS account (root user) has full permissions by default. As a result, any IAM policies can also give users and roles permission use the CMK for cryptographic operations.

16. (Optional) You can allow other AWS accounts to use this CMK for cryptographic operations. To do so, in the **Other AWS accounts** section at the bottom of the page, choose **Add another AWS account**

and enter the AWS account identification number of an external account. To add multiple external accounts, repeat this step.

**Note**

To allow principals in the external accounts to use the CMK, Administrators of the external account must create IAM policies that provide these permissions. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

17. Choose **Next**.
18. Review the key policy document that was created from your choices. You can edit it, too.
19. Choose **Finish** to create the CMK.

## Creating Symmetric CMKs (KMS API)

You can use the [CreateKey](#) operation to create a new symmetric customer master key (CMK). These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

This operation has no required parameters. However, you might also want to use the `Policy` parameter to specify a key policy. You can change the key policy ([PutKeyPolicy](#)) and add optional elements, such as a [description](#) and [tags](#) at any time. Also, if you are creating a CMK for [imported key material \(p. 147\)](#) or a CMK in a [custom key store \(p. 172\)](#), the `Origin` parameter is required.

The following is an example of a call to the `CreateKey` operation with no parameters. This command uses all of the default values. It creates a symmetric CMK for encrypting and decrypting with key material generated by AWS KMS.

```
$ aws kms create-key
{
  "KeyMetadata": {
    "Origin": "AWS_KMS",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Description": "",
    "KeyManager": "CUSTOMER",
    "Enabled": true,
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "KeyState": "Enabled",
    "CreationDate": 1502910355.475,
    "Arn": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "AWSAccountId": "111122223333"
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

If you do not specify a key policy for your new CMK, the [default key policy \(p. 51\)](#) that `CreateKey` applies differs from the default key policy that the console applies when you use it to create a new CMK.

For example, this call to the [GetKeyPolicy](#) operation returns the key policy that `CreateKey` applies. It gives the AWS account access to the CMK and allows it to create AWS Identity and Access Management (IAM) policies for the CMK. For detailed information about IAM policies and key policies for CMKs, see [Authentication and Access Control for AWS KMS \(p. 46\)](#)

```
$ aws kms get-key-policy --key-id 1234abcd-12ab-34cd-56ef-1234567890ab --policy-name
default --output text
{
  "Version" : "2012-10-17",
```

```
"Id" : "key-default-1",  
"Statement" : [ {  
  "Sid" : "Enable IAM User Permissions",  
  "Effect" : "Allow",  
  "Principal" : {  
    "AWS" : "arn:aws:iam::111122223333:root"  
  },  
  "Action" : "kms:*",  
  "Resource" : ""  
} ]  
}
```

## Creating Asymmetric CMKs

You can create [asymmetric CMKs \(p. 130\)](#) in the AWS Management Console or by using the AWS KMS API. An asymmetric CMK represents a public and private key pair that can be used for encryption or signing.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

If you are creating a CMK to encrypt data that you store or manage in an AWS service, use a symmetric CMK. AWS services that integrate with AWS KMS do not support asymmetric CMKs. For help deciding whether to create a symmetric or asymmetric CMK, see [How to Choose Your CMK Configuration \(p. 131\)](#).

### Creating Asymmetric CMKs (Console)

You can use the AWS Management Console to create asymmetric customer master keys (CMKs). Each asymmetric CMK represents a public and private key pair.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose **Create key**.
5. To create an asymmetric CMK, in **Key type**, choose **Asymmetric**.

For information about how to create an symmetric CMK in the AWS KMS console, see [Creating Symmetric CMKs \(Console\) \(p. 18\)](#).

6. To create an asymmetric CMK for public key encryption, in **Key usage**, choose **Encrypt and decrypt**. Or, to create an asymmetric CMK for signing messages and verifying signatures, in **Key usage**, choose **Sign and verify**.

For help choosing a key usage value, see [Selecting the Key Usage \(p. 132\)](#).

7. Select a specification (**Key spec**) for your asymmetric CMK.

Often the key spec that you select is determined by regulatory, security, or business requirements. It might also be influenced by the size of messages that you need to encrypt or sign. In general, longer encryption keys are more resistant to brute-force attacks.

For help choosing a key spec, see [Selecting the Key Spec \(p. 133\)](#).

8. Choose **Next**.

9. Type an alias for the CMK. The alias name cannot begin with **aws/**. The **aws/** prefix is reserved by Amazon Web Services to represent AWS managed CMKs in your account.

An alias is a display name that you can use to identify the CMK. We recommend that you choose an alias that indicates the type of data you plan to protect or the application you plan to use with the CMK.

Aliases are required when you create a CMK in the AWS Management Console. They are optional when you use the [CreateKey](#) operation.

10. (Optional) Type a description for the CMK.

Enter a description that explains the type of data you plan to protect or the application you plan to use with the CMK. Don't use the description format that's used for [AWS managed CMKs \(p. 4\)](#). The *Default master key that protects my ... when no other key is defined* description format is reserved for AWS managed CMKs.

You can add a description now or update it any time unless the [key state \(p. 223\)](#) is *Pending Deletion*. To add, change, or delete the description of an existing customer managed CMK, [edit the CMK \(p. 36\)](#) in the AWS Management Console or use the [UpdateKeyDescription](#) operation.

11. (Optional) Type a tag key and an optional tag value. To add more than one tag to the CMK, choose **Add tag**.

When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. For information about tagging CMKs, see [Tagging Keys \(p. 39\)](#).

12. Choose **Next**.

13. Select the IAM users and roles that can administer the CMK.

**Note**

IAM policies can give other IAM users and roles permission to manage the CMK.

14. (Optional) To prevent the selected IAM users and roles from deleting this CMK, in the **Key deletion** section at the bottom of the page, clear the **Allow key administrators to delete this key** check box.

15. Choose **Next**.

16. Select the IAM users and roles that can use the CMK for cryptographic operations.

**Note**

The AWS account (root user) has full permissions by default. As a result, any IAM policies can also give users and roles permission use the CMK for cryptographic operations.

17. (Optional) You can allow other AWS accounts to use this CMK for cryptographic operations. To do so, in the **Other AWS accounts** section at the bottom of the page, choose **Add another AWS account** and enter the AWS account identification number of an external account. To add multiple external accounts, repeat this step.

**Note**

To allow principals in the external accounts to use the CMK, Administrators of the external account must create IAM policies that provide these permissions. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

18. Choose **Next**.

19. Review the key policy document that was created from your choices. You can edit it, too.

20. Choose **Finish** to create the CMK.

## Creating Asymmetric CMKs (KMS API)

You can use the [CreateKey](#) operation to create an asymmetric customer master key (CMK). These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

When you create an asymmetric CMK, you must specify the `CustomerMasterKeySpec` parameter, which determines the type of keys you create. Also, you must specify a `KeyUsage` value of `ENCRYPT_DECRYPT` or `SIGN_VERIFY`. You cannot change these properties after the CMK is created.

The following example uses the `CreateKey` operation to create an asymmetric CMK of 4096-bit RSA keys designed for public key encryption.

```
$ aws kms create-key --customer-master-key-spec RSA_4096 --key-usage ENCRYPT_DECRYPT
{
  "KeyMetadata": {
    "KeyState": "Enabled",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "CustomerMasterKeySpec": "RSA_4096",
    "KeyManager": "CUSTOMER",
    "Description": "",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "CreationDate": 1569973196.214,
    "EncryptionAlgorithms": [
      "RSAES_OAEP_SHA_1",
      "RSAES_OAEP_SHA_256"
    ],
    "AWSAccountId": "111122223333",
    "Origin": "AWS_KMS",
    "Enabled": true
  }
}
```

The following example command creates an asymmetric CMK that represents a pair of ECDSA keys used for signing and verification. You cannot create an elliptic curve key pair for encryption and decryption.

```
$ aws kms create-key --customer-master-key-spec ECC_NIST_P521 --key-usage SIGN_VERIFY
{
  "KeyMetadata": {
    "KeyState": "Enabled",
    "KeyId": "0987dcba-09fe-87dc-65ba-ab0987654321",
    "CreationDate": 1570824817.837,
    "Origin": "AWS_KMS",
    "SigningAlgorithms": [
      "ECDSA_SHA_512"
    ],
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321",
    "AWSAccountId": "111122223333",
    "CustomerMasterKeySpec": "ECC_NIST_P521",
    "KeyManager": "CUSTOMER",
    "Description": "",
    "Enabled": true,
    "KeyUsage": "SIGN_VERIFY"
  }
}
```

## Viewing Keys

You can use [AWS Management Console](#) or the [AWS Key Management Service \(AWS KMS\) API](#) to view customer master keys (CMKs), including CMKs that you manage and CMKs that are managed by AWS.

### Topics

- [Viewing CMKs in the Console \(p. 23\)](#)

- [Viewing CMKs with the API \(p. 29\)](#)
- [Finding the Key ID and ARN \(p. 32\)](#)
- [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#)

## Viewing CMKs in the Console

In the AWS Management Console, you can view lists of your CMKs and details about each CMK.

### Topics

- [Navigating to the Key Tables \(p. 23\)](#)
- [Sorting and Filtering Your CMKs \(p. 23\)](#)
- [Displaying CMK Details \(p. 25\)](#)
- [Customizing Your CMK Tables \(p. 28\)](#)

## Navigating to the Key Tables

The AWS KMS customer master keys (CMKs) in each account and region are displayed in tables. There are separate tables for the CMKs that you create and the CMKs that AWS services create for you.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**. To view the keys in your account that AWS creates and manages for you, in the navigation pane, choose **AWS managed keys**. For information about the different types of CMKs, see [Customer master keys \(p. 2\)](#).

### Tip

To view [AWS managed CMKs \(p. 4\)](#) that are missing an alias, use the **Customer managed keys** page.

The AWS KMS console also displays the custom key stores in the account and Region. CMKs that you create in custom key stores appear on the **Customer managed keys** page. For information about custom key stores, see [Using a Custom Key Store \(p. 172\)](#).

## Sorting and Filtering Your CMKs

To make it easier to find your CMKs in the console, you can sort and filter them.

### Note

The **Key type** column is displayed only in AWS Regions where AWS KMS supports asymmetric CMKs and data key pairs.

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

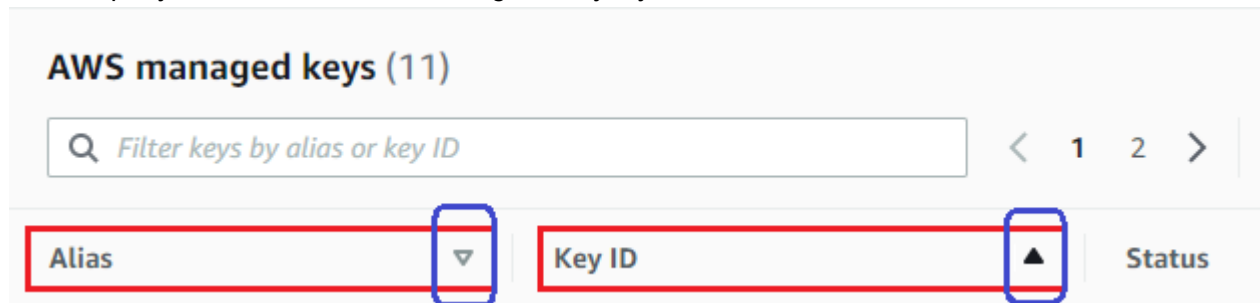

### Sort

You can sort customer managed CMKs in ascending or descending order by their column values. This feature sorts all CMKs in the table, even if they don't appear on the current table page.

Sortable columns are indicated by an arrow beside the column name. On the **AWS managed keys** page, you can sort by **Alias** or **Key ID**. On the **Customer managed keys** page, you can sort by **Alias**, **Key ID**, or **Key type**.

To sort in ascending order, choose the column heading until the arrow points upward. To sort in descending order, choose the column heading until the arrow points downward. You can only sort by one column at a time.

For example, you can sort CMKs in ascending order by key ID, instead of alias, which is the default.

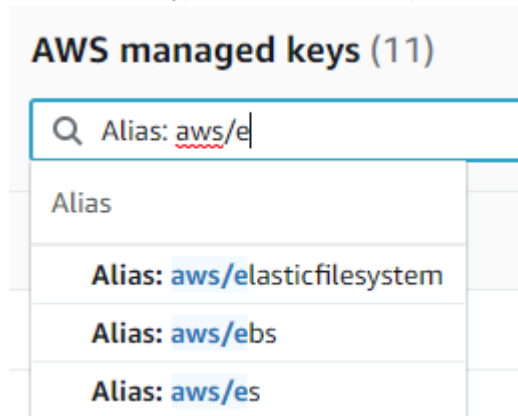

### Filter

You can filter CMKs by their column values. The filter applies to all CMKs in the table, even if they don't appear on the current table page. The filter is not case-sensitive.

Filterable columns are listed in the filter box. On the **AWS managed keys** page, you can filter by **Alias** and **Key ID**. On the **Customer managed keys** page, you can filter by **Alias**, **Key ID**, and **Key type**.

To filter by the value in a particular column, choose the filter, choose the column name, and then choose from the list of actual column values. After choosing a column, you can also type all or part of the column value. You'll see a preview of the results before you make your choice.

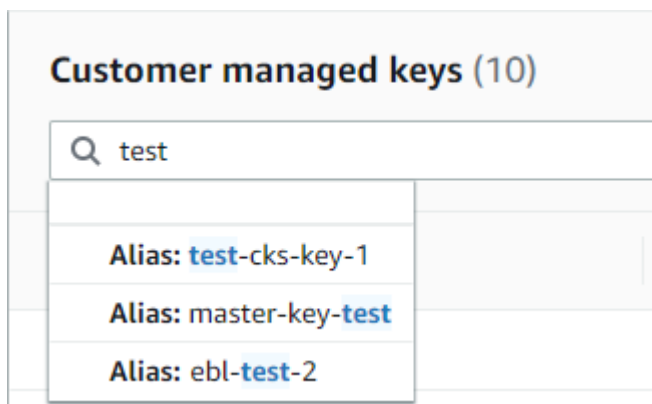

For example, to display CMKs with an alias name that contains with `aws/e`, choose the filter box, choose **Alias**, type `aws/e`, and then press `Enter` or `Return` to add the filter.

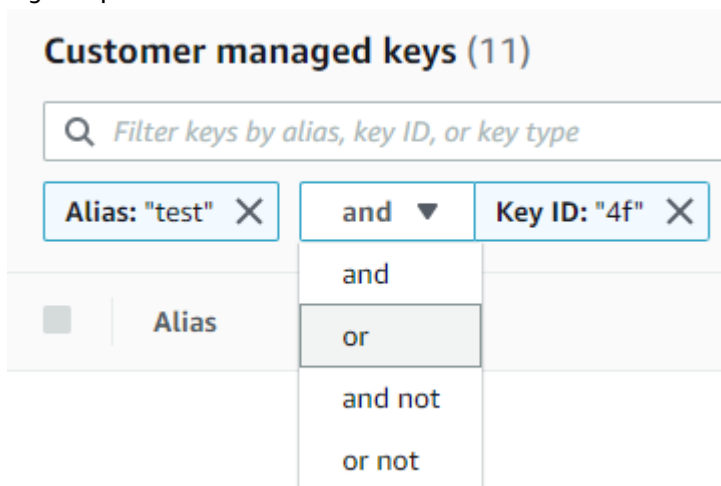

To search for text in all filterable columns, in the filter box, type all or part of a column value. You'll see a preview of the results before you make your choice.

For example, to display CMKs with `test` in any of the column values, type `test` in the filter box. The preview shows the CMKs that the filter will select. In this case, `test` appears only in the **Alias** column.

You can have multiple filters at the same time. When you add additional filters, you can also select a logical operator.

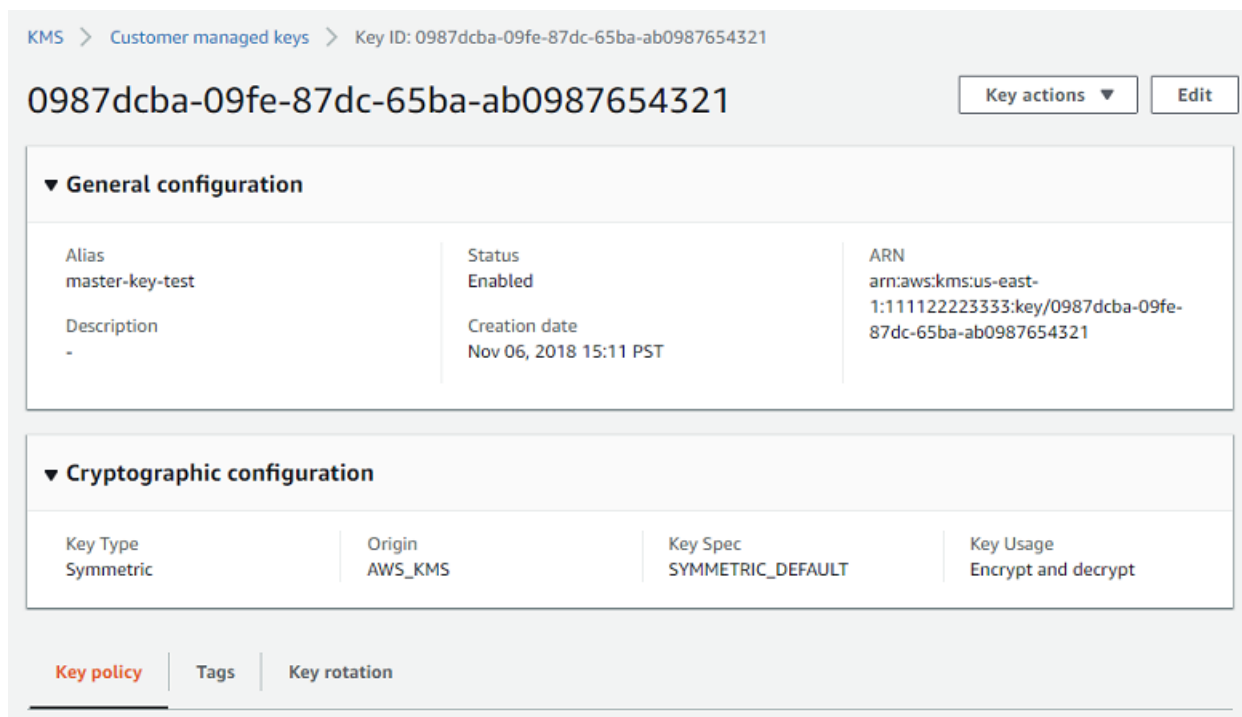

## Displaying CMK Details

The details page for each CMK displays the properties of the CMK. It differs slightly for the different types of CMKs.

To display detailed information about a CMK:

1. To display the details page for a CMK, on the **AWS managed keys** or **Customer managed keys** page, choose the alias or key ID of the CMK.
2. To display all details, expand the **General configuration** and **Cryptographic configuration** sections of the page. If the CMK is configured for imported key material, the page also has a **Key materials** section that you can expand.

The details page for a CMK includes a **General Configuration** section that displays the basic properties of the CMK, a **Cryptographic Configuration** section that displays the cryptographic properties of the CMK, and a tabbed display that includes the key policy, tags, key rotation (for symmetric CMKs), and public key (for asymmetric CMKs).

#### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

The following list describes the fields in the detailed display. Some of these fields are also available as columns in the table display.

#### Alias

A friendly name for the CMK. The **Alias** field in the console lists only one alias. To find all aliases for the CMK, use the [ListAliases](#) operation.

#### ARN

The Amazon Resource Name (ARN) of the CMK. This value uniquely identifies the CMK. You can use it to identify the CMK in AWS KMS API operations.

#### Creation date

The date and time that the CMK was created. This value is displayed in local time for the device. The time zone does not depend on the Region.

Unlike **Expiration**, the creation refers only to the CMK, not its key material.

#### CloudHSM cluster ID

The cluster ID of the AWS CloudHSM cluster that contains the key material for the CMK. This field appears only when the CMK is created in an AWS KMS [custom key store](#) (p. 172).

If you click the CloudHSM cluster ID, it opens the **Clusters** page in the AWS CloudHSM console.

### Custom key store ID

The ID of the [custom key store \(p. 172\)](#) that contains the CMK. This field appears only when the CMK is created in an AWS KMS custom key store.

If you click the custom key store ID, it opens the **Custom key stores** page in the AWS KMS console.

### Custom key store name

The name of the [custom key store \(p. 172\)](#) that contains the CMK. This field appears only when the CMK is created in an AWS KMS custom key store.

### Description

A brief, optional description of the CMK. To add or update the description of a customer managed CMK, above **General Configuration**, choose **Edit**.

### Encryption algorithms

Lists the encryption algorithms that can be used with the CMK in AWS KMS. The encryption algorithm restrictions are not enforceable outside of AWS KMS. This field appears only when the **Key type** is **Asymmetric** and the **Key usage** is **Encrypt and decrypt**.

### Expiration date

The date and time when the key material for the CMK expires. This field appears only for CMKs with [imported key material \(p. 147\)](#), that is, when the **Origin** is **External** and the CMK has key material that expires.

### Key policy

Controls access to the CMK along with [IAM policies \(p. 67\)](#) and [grants \(p. 115\)](#). Every CMK has one key policy. It is the only mandatory authorization element. To change the key policy of a customer managed CMK, on the **Key policy** tab, choose **Edit**. For details, see [the section called "Using Key Policies" \(p. 50\)](#).

### Key rotation

Enables and disables [automatic key rotation \(p. 142\)](#) every year.

To change the key rotation status of a [customer managed CMK \(p. 3\)](#), use the checkbox on the **Key rotation** tab. All [AWS managed CMKs \(p. 4\)](#) are automatically rotated every three years.

### Key spec

The type of key material in the CMK. AWS KMS supports symmetric CMKs (SYMMETRIC\_DEFAULT), CMKs for RSA keys of different lengths, and elliptic curve keys with different curves.

### Key type

Indicates whether the CMK is **Symmetric** or **Asymmetric**.

### Key usage

Indicates whether a CMK can be used for **Encrypt and decrypt** or **Sign and verify**. Only asymmetric CMKs can be used to sign and verify.

### Origin

The source of the key material for the CMK. Valid values are **AWS\_KMS** for key material that AWS KMS generates, **EXTERNAL** for [imported key material \(p. 147\)](#), and **AWS\_CloudHSM** for CMKs in [custom key stores \(p. 172\)](#).

### Public key

Displays the public key of an asymmetric CMK. Authorized users can use this tab to [copy and download the public key \(p. 43\)](#).

### Signing algorithms

Lists the signing algorithms that can be used with the CMK in AWS KMS. This field appears only when the **Key type** is **Asymmetric** and the **Key usage** is **Sign and verify**.

### Status

The key state of the CMK. You can use the CMK in cryptographic operations only when the status is **Enabled**. For a detailed description of each CMK status and its effect on the operations that you can run on the CMK, see [How Key State Affects Use of a Customer Master Key \(p. 223\)](#).

### Tags

Optional key-value pairs that describe the CMK. To add or change the tags for a CMK, on the **Tags** tab, choose **Edit**.

When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. For information about tagging CMKs, see [Tagging Keys \(p. 39\)](#).

## Customizing Your CMK Tables

You can customize the tables that appear on the **AWS managed keys** and **Customer managed keys** pages in the AWS Management Console to suit your needs. You can choose the table columns, the number of customer master keys (CMKs) on each page (**Page size**), and the text wrap. The configuration you choose is saved when you confirm it and reapplied whenever you open the pages.

### To customize your CMK tables

1. On the **AWS managed keys** or **Customer managed keys** page, choose the settings icon (  ) in the upper-right corner of the page.
2. On the **Preferences** page, choose your preferred settings, and then choose **Confirm**.

Consider using the **Page size** setting to increase the number of CMKs displayed on each page, especially if you typically use a device that's easy to scroll.

The data columns that you display might vary depending on the table, your job role, and the types of CMKs in the account and Region. The following table offers some suggested configurations. For descriptions of the columns, see [Displaying CMK Details \(p. 25\)](#).

### Suggested CMK Table Configurations

You can customize the columns that appear in your CMK table to display the information you need about your CMKs.

#### AWS managed keys

By default, the **AWS managed keys** table displays the **Alias**, **Key ID**, and **Status** columns. These columns are ideal for most use cases.

#### Symmetric customer managed keys

If you use only symmetric CMKs with key material generated by AWS KMS, the **Alias**, **Key ID**, **Status**, and **Creation date** columns are likely to be the most useful.

#### Asymmetric customer managed keys

If you use asymmetric CMKs, in addition to the **Alias**, **Key ID**, and **Status** columns, consider adding the **Key type**, **Key spec**, and **Key usage** columns. These columns will show you whether a CMK is

symmetric or asymmetric, the type of key material, and whether the CMK can be used for encryption or signing.

### Imported key material

If you have CMKs with [imported key material](#) (p. 147), in addition to the **Alias**, **Key ID**, and **Status** columns, consider adding the **Origin** and **Expiration date** columns. These columns will show you whether the key material in a CMK is imported or generated by AWS KMS and when the key material expires, if at all. The **Creation date** field displays the date that the CMK was created (without key material). It doesn't reflect any characteristic of the key material.

### Keys in custom key stores

If you have CMKs in [custom key stores](#) (p. 172), in addition to the **Alias**, **Key ID**, and **Status** columns, consider adding the **Custom key store ID** column. A value in this column indicates that the CMK is in a custom key store, as well as showing which custom key store it's in.

## Viewing CMKs with the API

You can use the [AWS Key Management Service \(AWS KMS\) API](#) to view your CMKs. This section demonstrates several operations that return details about existing CMKs. The examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

### Topics

- [ListKeys: Get the ID and ARN of All CMKs](#) (p. 29)
- [DescribeKey: Get Detailed Information About a CMK](#) (p. 30)
- [GetKeyPolicy: Get the Key Policy Attached to a CMK](#) (p. 31)
- [ListAliases: View CMKs by Alias Name](#) (p. 31)

## ListKeys: Get the ID and ARN of All CMKs

The [ListKeys](#) operation returns the ID and Amazon Resource Name (ARN) of all CMKs in the account and Region.

For example, this call to the `ListKeys` operation returns the ID and ARN of each CMK in this fictitious account.

```
$ aws kms list-keys

{
  "Keys": [
    {
      "KeyArn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
    },
    {
      "KeyArn": "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321",
      "KeyId": "0987dcba-09fe-87dc-65ba-ab0987654321"
    },
    {
      "KeyArn": "arn:aws:kms:us-east-2:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d",
      "KeyId": "1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d"
    }
  ]
}
```

## DescribeKey: Get Detailed Information About a CMK

The [DescribeKey](#) operation returns details about the specified CMK. To identify the CMK, use its key ID, key ARN, alias name, or alias ARN.

For example, this call to `DescribeKey` returns information about a symmetric CMK. The fields in the response vary with the customer master key spec, key state, and the origin.

```
$ aws kms describe-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab

{
  "KeyMetadata": {
    "Origin": "AWS_KMS",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Description": "",
    "KeyManager": "CUSTOMER",
    "Enabled": true,
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "KeyState": "Enabled",
    "CreationDate": 1499988169.234,
    "Arn": "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "AWSAccountId": "11112223333"
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

This example calls `DescribeKey` operation on an asymmetric CMK used for signing and verification. The response includes the signing algorithms that AWS KMS supports for this CMK.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

```
$ aws kms describe-key --key-id 0987dcba-09fe-87dc-65ba-ab0987654321

{
  "KeyMetadata": {
    "KeyId": "0987dcba-09fe-87dc-65ba-ab0987654321",
    "Origin": "AWS_KMS",
    "Arn": "arn:aws:kms:us-west-2:11112223333:key/0987dcba-09fe-87dc-65ba-ab0987654321",
    "KeyState": "Enabled",
    "KeyUsage": "SIGN_VERIFY",
    "CreationDate": 1569973196.214,
    "Description": "",
    "CustomerMasterKeySpec": "ECC_NIST_P521",
    "AWSAccountId": "11112223333",
    "Enabled": true,
    "KeyManager": "CUSTOMER"
    "SigningAlgorithms": [
      "ECDSA_SHA_512"
    ]
  }
}
```

You can use the `DescribeKey` operation on a predefined AWS alias, that is, an AWS alias with no key ID. When you do, AWS KMS associates the alias with an [AWS managed CMK \(p. 2\)](#) and returns its `KeyId` and `Arn` in the response.

## GetKeyPolicy: Get the Key Policy Attached to a CMK

The `GetKeyPolicy` operation gets the key policy that is attached to the CMK. To identify the CMK, use its key ID or key ARN. You must also specify the policy name, which is always `default`. (If your output is difficult to read, add the `--output text` option to your command.)

```
$ aws kms get-key-policy --key-id 1234abcd-12ab-34cd-56ef-1234567890ab --policy-name
default

{
  "Version" : "2012-10-17",
  "Id" : "key-default-1",
  "Statement" : [ {
    "Sid" : "Enable IAM User Permissions",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::111122223333:root"
    },
    "Action" : "kms:*",
    "Resource" : "*"
  } ]
}
```

## ListAliases: View CMKs by Alias Name

The `ListAliases` operation returns aliases in the account and region. The `TargetKeyId` in the response displays the key ID of the CMK that the alias refers to, if any.

By default, the `ListAliases` command returns all aliases in the account and region. This includes [aliases that you created](#) and associated with your [customer managed CMKs \(p. 2\)](#), and aliases that AWS created and associated with [AWS managed CMKs \(p. 2\)](#) in your account. You can recognize AWS aliases because their names have the format `aws/<service-name>`, such as `aws/dynamodb`.

The response might also include aliases that have no `TargetKeyId` field, such as the `aws/redshift` alias in this example. These are predefined aliases that AWS has created but has not yet associated with a CMK.

```
$ aws kms list-aliases

{
  "Aliases": [
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/ImportedKey",
      "TargetKeyId": "0987dcba-09fe-87dc-65ba-ab0987654321",
      "AliasName": "alias/ExampleKey"
    },
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/test-key",
      "TargetKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
      "AliasName": "alias/test-key"
    },
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/financeKey",
      "TargetKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
      "AliasName": "alias/financeKey"
    }
  ]
}
```

```
{
  "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/aws/dynamodb",
  "TargetKeyId": "1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d",
  "AliasName": "alias/aws/dynamodb"
},
{
  "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/aws/redshift",
  "AliasName": "alias/aws/redshift"
},
{
  "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/aws/s3",
  "TargetKeyId": "0987ab65-43cd-21ef-09ab-87654321cdef",
  "AliasName": "alias/aws/s3"
}
]
```

To get the aliases that refer to a particular CMK, use the `KeyId` parameter. The parameter value can be the Amazon Resource Name (ARN) of the CMK or the CMK ID. You cannot specify an alias or alias ARN.

The command in the following example gets the aliases that refer to a customer managed CMK. But you can use a command like this one to find the aliases that refer to AWS managed CMKs, too.

```
$ aws kms list-aliases --key-id arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

{
  "Aliases": [
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/test-key",
      "TargetKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
      "AliasName": "alias/test-key"
    },
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/financeKey",
      "TargetKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
      "AliasName": "alias/financeKey"
    }
  ]
}
```

## Finding the Key ID and ARN

To identify your AWS KMS CMKs in programs, scripts, and command line interface (CLI) commands, you use the ID of the CMK or its Amazon Resource Name (ARN). Cryptographic operations also let you use the CMK alias.

### To find the CMK ID and ARN (Console)

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**. To view the keys in your account that AWS creates and manages for you, in the navigation pane, choose **AWS managed keys**.
4. To find the key ID for a CMK, see the row that begins with the CMK alias.

The **Key ID** column appears in the tables by default. If the Key ID column doesn't appear in your table, use the procedure described in [the section called "Customizing Your CMK Tables" \(p. 28\)](#) to restore it. You can also view the key ID of a CMK on its details page.

Customer managed keys					Key actions ▼	Create
<input type="text"/>						
<input type="checkbox"/>	Alias ▲	Key ID ▼	Status	Creation date		
<input type="checkbox"/>	master-key-test	1234abcd-12ab-34cd-56ef-1234567890ab	Enabled	Oct 19, 2018 1		

5. To find the Amazon Resource Name (ARN) of the CMK, choose the key ID or alias. The key ARN appears in the **General Configuration** section.

General configuration		
Alias master-key-test	Status Enabled	ARN arn:aws:kms:us-east-1:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
Description -	Creation date Nov 06, 2018 15:11 PST	

## To find the CMK ID and ARN (KMS API)

### Use the ListKeys API operation

- To find the CMK ID and ARN, use the [ListKeys \(p. 29\)](#) operation.

## Identifying Symmetric and Asymmetric CMKs

To determine whether a particular CMK is [symmetric or asymmetric \(p. 129\)](#), find its *key type* or *key spec* ([p. 10](#)). You can use the AWS KMS console or AWS KMS API.

Some of these methods will also show you other aspects of the cryptographic configuration of a CMK, including its key usage and the encryption or signing algorithms that the CMK supports. You can view the cryptographic configuration of an existing CMK, but you cannot change it.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

For general information about viewing CMKs, including sorting, filtering, and choosing columns for your console display, see [Viewing CMKs in the Console \(p. 23\)](#).

### Topics

- [Finding the Key Type in the CMK Table \(p. 34\)](#)
- [Finding the Key Type on the Details Page \(p. 34\)](#)
- [Finding the Key Spec Using the AWS KMS API \(p. 35\)](#)

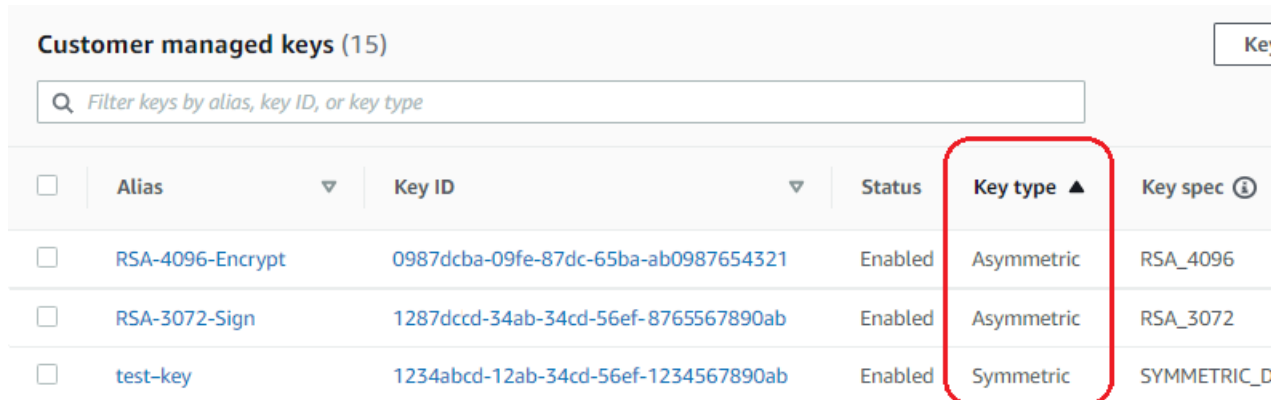

## Finding the Key Type in the CMK Table

In the AWS KMS console, the **Key type** column shows whether each CMK is symmetric or asymmetric. You can add a **Key type** column to the CMK table on the **Customer managed keys** or **AWS managed keys** pages in the console.

To identify symmetric and asymmetric CMKs in your CMK table, use the following procedure.

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**. To view the keys in your account that AWS creates and manages for you, in the navigation pane, choose **AWS managed keys**.
4. The **Key type** column shows whether each CMK is symmetric or asymmetric. You can also [sort and filter \(p. 23\)](#) by the **Key type** value.

If the **Key type** column does not appear in your CMK table, choose the gear icon in the upper right corner of the page, choose **Key type**, and then choose **Confirm**. You can also add the **Key spec** and **Key usage** columns.

Filter keys by alias, key ID, or key type					
<input type="checkbox"/>	Alias ▾	Key ID ▾	Status	Key type ▲	Key spec ⓘ
<input type="checkbox"/>	RSA-4096-Encrypt	0987dcba-09fe-87dc-65ba-ab0987654321	Enabled	Asymmetric	RSA_4096
<input type="checkbox"/>	RSA-3072-Sign	1287dccc-34ab-34cd-56ef-8765567890ab	Enabled	Asymmetric	RSA_3072
<input type="checkbox"/>	test-key	1234abcd-12ab-34cd-56ef-1234567890ab	Enabled	Symmetric	SYMMETRIC_D

## Finding the Key Type on the Details Page

In the AWS KMS console, the details page for each CMK includes a **Cryptographic Configuration** section that displays the key type (symmetric or asymmetric) and other cryptographic details about the CMK.

To identify symmetric and asymmetric CMKs on the details page for a CMK, use the following procedure.

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**. To view the keys in your account that AWS creates and manages for you, in the navigation pane, choose **AWS managed keys**.
4. Choose the alias or key ID of a CMK.
5. Choose **Cryptographic configuration**.

The **Cryptographic configuration** section includes the **Key Type**, which indicates whether it is symmetric or asymmetric. It also displays other details about the CMK, including the **Key Usage**, which tells whether a CMK can be used for encryption and decryption or signing and verification. For asymmetric CMKs, it displays the encryption algorithms or signing algorithms that the CMK supports.

For example, the following is an example **Cryptographic configuration** section for a symmetric CMK.

▼ Cryptographic configuration			
Key Type Symmetric	Origin AWS_KMS	Key Spec ⓘ SYMMETRIC_DEFAULT	Key Usage Encrypt and decrypt

The following is an example **Cryptographic configuration** section for an asymmetric RSA CMK that's used for signing and verification.

▼ Cryptographic configuration		
Key Type Asymmetric	Key Spec ⓘ RSA_2048	Signing algorithms RSASSA_PKCS1_V1_5_SHA_256 RSASSA_PKCS1_V1_5_SHA_384 RSASSA_PKCS1_V1_5_SHA_512 RSASSA_PSS_SHA_256 RSASSA_PSS_SHA_384 RSASSA_PSS_SHA_512
Origin AWS_KMS	Key Usage Sign and verify	

## Finding the Key Spec Using the AWS KMS API

To determine whether a CMK is symmetric or asymmetric, use the [DescribeKey](#) operation. The `CustomerMasterKeySpec` field in the response contains the [key spec](#) (p. 10) of the CMK. For a symmetric CMK, the value of `CustomerMasterKeySpec` is `SYMMETRIC_DEFAULT`. All other values indicate an asymmetric CMK.

For example, `DescribeKey` returns the following response for a symmetric CMK. The `CustomerMasterKeySpec` value is `SYMMETRIC_DEFAULT`.

```
{
  "KeyMetadata": {
    "AWSAccountId": "111122223333",
    "KeyId": "0987dcba-09fe-87dc-65ba-ab0987654321",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321",
    "CreationDate": 1496966810.831,
    "Enabled": true,
    "Description": "",
    "KeyState": "Enabled",
    "Origin": "AWS_KMS",
    "KeyManager": "CUSTOMER",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

The `DescribeKey` response for an asymmetric RSA CMK used in signing and verification looks similar to this example. The `CustomerMasterKeySpec` value is `RSA_2048`. To learn more about this key spec, see [RSA Key Specs](#) (p. 134).

```
{
  "KeyMetadata": {
    "AWSAccountId": "111122223333",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "CreationDate": 1571767572.317,
    "Enabled": false,
    "Description": "",
    "KeyState": "Disabled",
    "Origin": "AWS_KMS",
    "KeyManager": "CUSTOMER",
    "CustomerMasterKeySpec": "RSA_2048",
    "KeyUsage": "SIGN_VERIFY",
    "SigningAlgorithms": [
      "RSASSA_PKCS1_V1_5_SHA_256",
      "RSASSA_PKCS1_V1_5_SHA_384",
      "RSASSA_PKCS1_V1_5_SHA_512",
      "RSASSA_PSS_SHA_256",
      "RSASSA_PSS_SHA_384",
      "RSASSA_PSS_SHA_512"
    ]
  }
}
```

## Editing Keys

You can use the AWS KMS API and the key detail page of the AWS Management Console to edit some of the properties of your customer managed [customer master keys \(p. 2\)](#) (CMKs). You can change the description, add and remove administrators and users, manage tags, and enable and disable key rotation.

You cannot change the properties of [AWS managed CMKs \(p. 2\)](#).

### Topics

- [Editing CMKs \(Console\) \(p. 36\)](#)
- [Editing CMKs \(KMS API\) \(p. 38\)](#)

## Editing CMKs (Console)

Users who have the required permissions can change the properties of a customer managed CMK, including its description, tags, policies and grants, and rotation status in the AWS Management Console.

You can [view \(p. 22\)](#), but not edit, the properties of AWS managed CMKs. To view the key policy for an AWS managed CMK, use the [GetKeyPolicy](#) operation.

### Navigate to the CMK details page

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**. (You cannot edit the properties of AWS managed keys.)
4. Choose the alias or key ID of the CMK that you want to edit. Now, use the controls on the key details page to view and change the properties of the CMK.

## Change the CMK description

You can add, change, or delete the description of your CMK unless its [key state \(p. 223\)](#) is Pending Deletion. The description is optional.

1. In the upper-right corner, choose **Edit**.
2. For **Description**, type a brief description of the CMK. You can also delete an existing description.

Enter a description that explains the type of data you plan to protect or the application you plan to use with the CMK. The *Default master key that protects my ... when no other key is defined* description format is reserved for [AWS managed CMKs \(p. 4\)](#).

3. To save your changes, choose **Save**.

## Change CMK administrators and users

You can change the key policy for your CMK. Key policies define the IAM users, groups, and roles that can manage the CMK and use it for cryptographic operations.

The AWS account (root user) has full permissions by default. As a result, any IAM users and roles whose attached policies allow the appropriate permissions can also administer the CMK. For detailed information about setting key policies and IAM policies, see [Authentication and Access Control for AWS KMS \(p. 46\)](#).

1. On the details page for CMK, choose the **Key policy** tab.

If the key policy for the CMK is a default policy, the **Key policy** tab displays the default view with **Key administrators**, **Key deletion**, **Key users**, and **Other AWS accounts** sections. Otherwise, the tab displays the key policy document.

To edit the key policy document directly, choose **Switch to policy view** (if applicable), choose **Edit**, edit the document, then choose **Save**.

The remaining steps in this procedure explain how to edit the key policy using the default view.

2. To change the users and roles who can manage the CMK, use the **Key administrators** section.
  - To add a key administrator, choose **Add**, choose or type a user or role, then choose **Add**.
  - To remove a key administrator, check the box for the user or role, then choose **Remove**.
3. To prevent the key administrators from scheduling deletion of the CMK, in the **Key deletion** section, clear the **Allow key administrators to delete this key** check box.
4. To change the users and roles who can use the CMK in cryptographic operations, use the **Key users** section.
  - To add a key user, choose **Add**, choose a user or role, then choose **Add**.
  - To remove a key user, check the box for the user or role, then choose **Remove**.
5. To change the other AWS accounts that can use the CMK in cryptographic operations, in the **Other AWS accounts** section, choose **Add other AWS accounts**.

### Note

Adding an external account does not allow users and roles in the account to use the CMK. To allow users and roles in an external account to use the CMK, an administrator of the external account must add IAM policies that provide these permissions. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

- To add accounts, choose **Add another AWS account**, type the account number.
- To remove accounts, on the row with the account number, choose **Remove**.

When you are done, choose **Save changes**, then click the **X** to close the window.

### Add, edit, and delete tags

You can change the tags for your CMK. Each tag is a name–value pair. The tag name must be unique in the account and region.

You can use tags to identify and categorize your CMKs. When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. For more information about CMK tags, see [Tagging Keys \(p. 39\)](#).

- On the details page for CMK, choose the **Tags** tab.
  - To create your first tag, choose **Create tag**, type a tag name and tag value, and then choose **Save**.
  - To add a tag, choose **Edit**, choose **Add tag**, type a tag name and tag value, and then choose **Save**.
  - To change the name or value of a tag, choose **Edit**, make your changes, and then choose **Save**.
  - To delete a tag, choose **Edit**. On the tag row, choose **Remove**, and then choose **Save**.

### Enable or disable rotation

You can enable and disable [automatic rotation \(p. 142\)](#) of the cryptographic material in a symmetric [customer managed CMK \(p. 2\)](#). This feature is not supported for asymmetric CMKs or for CMKs with imported key material.

#### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

[AWS managed CMKs \(p. 2\)](#) are automatically rotated every three years. You cannot enable or disable this feature.

1. On the details page for CMK, choose the **Key rotation** tab.
2. To enable automatic key rotation, check the **Automatically rotate this CMK every year** check box. To disable automatic key rotation, clear the check box.
3. To save your changes, choose **Save**.

## Editing CMKs (KMS API)

You can use the [AWS Key Management Service \(AWS KMS\) API](#) to edit the properties of your [customer managed CMKs \(p. 2\)](#). These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language. This section demonstrates several operations that return details about existing CMKs.

You cannot edit the properties of [AWS managed CMKs \(p. 2\)](#).

### Topics

- [UpdateKeyDescription: Change the Description of a CMK \(p. 39\)](#)
- [PutKeyPolicy: Change the Key Policy for a CMK \(p. 39\)](#)
- [Enable and Disable Key Rotation \(p. 39\)](#)

#### Tip

For information about adding, deleting, and editing tags, see [Tagging Keys \(p. 39\)](#).

## UpdateKeyDescription: Change the Description of a CMK

The [UpdateKeyDescription](#) operation replaces the description of the CMK with the one that you specify. You can use it to add, change, or delete the description of a CMK. To see the description, use the [DescribeKey](#) operation.

For example, this call to the `UpdateKeyDescription` operation changes the description of the specified CMK.

```
$ aws kms update-key-description --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
                                --description "Example key"
```

To get the description of a key, use the `DescribeKey` operation, as shown in the following example.

```
$ aws kms describe-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab

{
  "KeyMetadata": {
    "Origin": "AWS_KMS",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Description": "Example key",
    "KeyManager": "CUSTOMER",
    "Enabled": true,
    "KeyUsage": "ENCRYPT_DECRYPT",
    "KeyState": "Enabled",
    "CreationDate": 1499988169.234,
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "AWSAccountId": "111122223333",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

## PutKeyPolicy: Change the Key Policy for a CMK

The [PutKeyPolicy](#) operation changes the key policy of the CMK to the policy that you specify. The policy includes permissions for administrators, users, and roles. For a detailed example, see [PutKeyPolicy Examples](#).

## Enable and Disable Key Rotation

The [EnableKeyRotation](#) operation enables [automatic rotation](#) (p. 142) of the cryptographic material in a symmetric CMK. The [DisableKeyRotation](#) operation disables it. The [GetKeyRotationStatus](#) operation returns a Boolean value that tells you whether automatic key rotation is enabled (**true**) or disabled (**false**).

For an example, see [Rotating Customer Master Keys](#) (p. 142).

## Tagging Keys

You can add, change, and delete tags for [customer managed CMKs](#) (p. 2). Each tag consists of a *tag key* and a *tag value* that you define. For example, the tag key might be "Cost Center" and the tag value might be "87654." You cannot tag [AWS managed CMKs](#) (p. 2).

When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. You can use this feature to track AWS KMS costs for a project, application, or cost center.

For more information about using tags for cost allocation, see [Using Cost Allocation Tags](#) in the *AWS Billing and Cost Management User Guide*. For information about the rules that apply to tag keys and tag values, see [User-Defined Tag Restrictions](#) in the *AWS Billing and Cost Management User Guide*.

#### Topics

- [Managing CMK Tags \(Console\) \(p. 40\)](#)
- [Managing CMK Tags \(KMS API\) \(p. 40\)](#)

## Managing CMK Tags (Console)

You can add, edit, and delete tags for your customer managed CMKs in the AWS Management Console. You can add tags to a CMK when you [create it \(p. 17\)](#) and edit them at any time. You cannot edit the tags of CMKs that are pending deletion. For more information, see [Editing Keys \(p. 36\)](#).

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**. (You cannot manage the tags of an AWS managed CMK.)
4. Select the check box next to the alias of a CMK.
5. Choose **Key actions**, **Add or edit tags**.
6. Use the controls to add, edit, or delete tags. The tag name must be unique in the account and region.
7. To save your changes, choose **Save changes**.

## Managing CMK Tags (KMS API)

You can use the [AWS Key Management Service \(AWS KMS\) API](#) to add, delete, and list tags for the CMKs that you manage. These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

You cannot tag AWS managed CMKs.

#### Topics

- [TagResource: Add or Change Tags for a CMK \(p. 40\)](#)
- [ListResourceTags: Get the Tags for a CMK \(p. 41\)](#)
- [UntagResource: Delete Tags from a CMK \(p. 41\)](#)

## TagResource: Add or Change Tags for a CMK

The [TagResource](#) operation adds one or more tags to a CMK.

You can also use **TagResource** to change the values for an existing tag. To replace tag values, specify the same tag key with different values. To add values to a tag, specify the tag key with both new and existing values.

For example, this call to the **TagResource** operation adds **Purpose** and **Department** tags to the specified CMK. You can use any keys and values as CMK tags.

```
$ aws kms tag-resource --key-id 1234abcd-12ab-34cd-56ef-1234567890ab /  
                        --tags TagKey=Purpose,TagValue=Test /  
                        TagKey=Department,TagValue=Finance
```

When this command is successful, it does not return any output. To view the tags on a CMK, use the [ListResourceTags](#) operation.

## ListResourceTags: Get the Tags for a CMK

The [ListResourceTags](#) operation gets the tags for a CMK. The `key-id` parameter is required.

For example, the following command gets the tags for the specified CMK.

```
$ aws kms list-resource-tags --key-id 1234abcd-12ab-34cd-56ef-1234567890ab  
  
    "Truncated": false,  
    "Tags": [  
      {  
        "TagKey": "Purpose",  
        "TagValue": "Test"  
      },  
      {  
        "TagKey": "Department",  
        "TagValue": "Finance"  
      }  
    ]  
  }
```

## UntagResource: Delete Tags from a CMK

The [UntagResource](#) operation deletes tags from a CMK. The `key-id` and `tag-keys` parameters are required.

For example, this command deletes the **Purpose** tag and all of its values from the specified CMK.

```
$ aws kms untag-resource --tag-keys Purpose --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

When this command is successful, it does not return any output.

# Enabling and Disabling Keys

You can disable and reenable the [customer master keys \(p. 2\)](#) (CMKs) that you manage. You cannot enable or disable AWS managed CMKs.

When you create a CMK, it is enabled by default. If you disable a CMK, it cannot be used to encrypt or decrypt data until you re-enable it. AWS managed CMKs are permanently enabled for use by [services that use AWS KMS \(p. 228\)](#). You cannot disable them.

You can also delete CMKs. For more information, see [Deleting Customer Master Keys \(p. 160\)](#).

### Note

AWS KMS does not rotate the backing keys of customer managed CMKs while they are disabled. For more information, see [How Automatic Key Rotation Works \(p. 143\)](#).

## Topics

- [Enabling and Disabling CMKs \(Console\) \(p. 42\)](#)
- [Enabling and Disabling CMKs \(KMS API\) \(p. 42\)](#)

## Enabling and Disabling CMKs (Console)

You can enable and disable customer managed CMKs from the IAM section of the AWS Management Console.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Select the check box for the CMKs that you want to enable or disable.
5. To enable a CMK, choose **Key actions**, **Enable**. To disable a CMK, choose **Key actions**, **Disable**.

## Enabling and Disabling CMKs (KMS API)

The [EnableKey](#) operation enables a disabled AWS KMS customer master key (CMK). These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language. The `key-id` parameter is required.

This operation does not return any output. To see the key status, use the [DescribeKey](#) operation.

```
$ aws kms enable-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

The [DisableKey](#) operation disables an enabled CMK. The `key-id` parameter is required.

```
$ aws kms disable-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

This operation does not return any output. To see the key status, use the [DescribeKey](#) operation, and see the `Enabled` field.

```
$ aws kms describe-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
{
  "KeyMetadata": {
    "Origin": "AWS_KMS",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Description": "",
    "KeyManager": "CUSTOMER",
    "Enabled": false,
    "KeyState": "Disabled",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "CreationDate": 1502910355.475,
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "AWSAccountId": "111122223333",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

## Downloading Public Keys

You can view, copy, and download the public key from an asymmetric CMK pair by using the AWS Management Console or the AWS KMS API. You must have `kms:GetPublicKey` permission on the asymmetric CMK.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

Each asymmetric CMK pair consists of a private key that never leaves AWS KMS unencrypted and a public key that you can download and share.

You might share a public key to let others encrypt data outside of AWS KMS that you can decrypt only with your private key. Or, to allow others to verify a digital signature outside of AWS KMS that you have generated with your private key.

When you use the public key in your asymmetric CMK within AWS KMS, you benefit from the authentication, authorization, and logging that are part of every AWS KMS operation. You also reduce of risk of encrypting data that cannot be decrypted. These features are not effective outside of AWS KMS. For details, see [Special Considerations for Downloading Public Keys \(p. 43\)](#).

### Topics

- [Special Considerations for Downloading Public Keys \(p. 43\)](#)
- [Downloading a Public Key \(Console\) \(p. 44\)](#)
- [Downloading a Public Key \(KMS API\) \(p. 44\)](#)

## Special Considerations for Downloading Public Keys

To protect your CMKs, AWS KMS provides access controls, authenticated encryption, and detailed logs of every operation. AWS KMS also allows you to prevent the use of CMKs, temporarily or permanently. Finally, AWS KMS operations are designed to minimize of risk of encrypting data that cannot be decrypted. These features are not available when you use downloaded public keys outside of AWS KMS.

### Authorization

[Key policies \(p. 50\)](#) and [IAM policies \(p. 67\)](#) that control access to the CMK within AWS KMS have no effect on operations performed outside of AWS. Any user who can get the public key can use it outside of AWS KMS even if they don't have permission to encrypt data or verify signatures with the CMK.

### Key Usage Restrictions

Key usage restrictions are not effective outside of AWS KMS. If you call the [Encrypt](#) operation with a CMK that has a `KeyUsage` of `SIGN_VERIFY`, the AWS KMS operation fails. But if you encrypt data outside of AWS KMS with a public key from an CMK with a `KeyUsage` of `SIGN_VERIFY`, the data cannot be decrypted.

### Algorithm Restrictions

Restrictions on the encryption and signing algorithms that AWS KMS supports are not effective outside of AWS KMS. If you encrypt data with the public key from a CMK outside of AWS KMS, and use an encryption algorithm that AWS KMS does not support, the data cannot be decrypted.

### Disabling and Deleting CMKs

Actions that you can take to prevent the use of CMK in a cryptographic operation within AWS KMS do not prevent anyone from using the public key outside of AWS KMS. For example, disabling a CMK,

scheduling deletion of a CMK, deleting a CMK, or deleting the key material from a CMK have no effect on a public key outside of AWS KMS. If you delete an asymmetric CMK or delete or lose its key material, data that you encrypt with a public key outside of AWS KMS is unrecoverable.

### Logging

AWS CloudTrail logs that record every AWS KMS operation, including the request, response, date, time, and authorized user, do not record the use of the public key outside of AWS KMS.

## Downloading a Public Key (Console)

You can use the AWS Management Console to view, copy, and download the public key from an asymmetric CMK in your AWS account. To download the public key from an asymmetric CMK in different AWS account, use the AWS KMS API.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose the alias or key ID of an asymmetric CMK.
5. From the **Cryptographic configuration** section, record the values of the **Key spec**, **Key usage**, and **Encryption algorithms** or **Signing Algorithms** fields. You'll need to use these values to use the public key outside of AWS KMS. Be sure to share this information when you share the public key.
6. Choose the **Public key** tab.
7. To copy the public key to your clipboard, choose **Copy**. To download the public key to a file, choose **Download**.

## Downloading a Public Key (KMS API)

The `GetPublicKey` operation returns the public key in an asymmetric CMK. It also returns critical information that you need to use the public key correctly outside of AWS KMS, including the key usage and encryption algorithms. Be sure to save these values and share them whenever you share the public key.

The examples in this section use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

To specify a CMK, use its key ID, Amazon Resource Name (ARN), alias name, or alias ARN. When using an alias name, prefix it with **alias/**. To specify a CMK in a different AWS account, you must use its key ARN or alias ARN.

Before running this command, replace the example alias name with a valid identifier for the CMK. To run this command, you must have `kms:GetPublicKey` permissions on the CMK.

```
$ aws kms get-public-key --key-id alias/example_RSA_3072

{
  "CustomerMasterKeySpec": "RSA_3072",
  "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "KeyUsage": "ENCRYPT_DECRYPT",
  "EncryptionAlgorithms": [
    "RSAES_OAEP_SHA_1",
    "RSAES_OAEP_SHA_256"
  ],
  "PublicKey": "MIIBOjANBgkqhkiG..."
```

```
}
```

# Authentication and Access Control for AWS KMS

Access to AWS KMS requires credentials that AWS can use to authenticate your requests. The credentials must have permissions to access AWS resources, such as AWS KMS customer master keys (CMKs). The following sections provide details about how you can use AWS Identity and Access Management (IAM) and AWS KMS to help secure your resources by controlling who can access them.

## Topics

- [Authentication](#) (p. 46)
- [Access Control](#) (p. 47)

## Authentication

You can access AWS as any of the following types of identities:

- **AWS account root user** – When you sign up for AWS, you provide an email address and password for your AWS account. These are your *root credentials* and they provide complete access to all of your AWS resources.

### Important

For security reasons, we recommend that you use the root credentials only to create an *administrator user*, which is an *IAM user* with full permissions to your AWS account. Then, you can use this administrator user to create other IAM users and roles with limited permissions. For more information, see [Create Individual IAM Users \(IAM Best Practices\)](#) and [Creating An Admin User and Group](#) in the *IAM User Guide*.

- **IAM user** – An [IAM user](#) is an identity within your AWS account that has specific permissions (for example, to use a KMS CMK). You can use an IAM user name and password to sign in to secure AWS webpages like the [AWS Management Console](#), [AWS Discussion Forums](#), or the [AWS Support Center](#).

In addition to a user name and password, you can also create [access keys](#) for each user to enable the user to access AWS services programmatically, through [one of the AWS SDKs](#) or the [command line tools](#). The SDKs and command line tools use the access keys to cryptographically sign API requests. If you don't use the AWS tools, you must sign API requests yourself. AWS KMS supports *Signature Version 4*, an AWS protocol for authenticating API requests. For more information about authenticating API requests, see [Signature Version 4 Signing Process](#) in the *AWS General Reference*.

- **IAM role** – An [IAM role](#) is another IAM identity you can create in your account that has specific permissions. It is similar to an IAM user, but it is not associated with a specific person. An IAM role enables you to obtain temporary access keys to access AWS services and resources programmatically. IAM roles are useful in the following situations:

- **Federated user access** – Instead of creating an IAM user, you can use preexisting user identities from [AWS Directory Service](#), your enterprise user directory, or a web identity provider. These are known as *federated users*. Federated users use IAM roles through an [identity provider](#). For more information about federated users, see [Federated Users and Roles](#) in the *IAM User Guide*.
- **Cross-account access** – You can use an IAM role in your AWS account to allow another AWS account permissions to access your account's resources. For an example, see [Tutorial: Delegate Access Across AWS Accounts Using IAM Roles](#) in the *IAM User Guide*.
- **AWS service access** – You can use an IAM role in your account to allow an AWS service permissions to access your account's resources. For example, you can create a role that allows Amazon Redshift to access an S3 bucket on your behalf and then load data stored in the S3 bucket into an Amazon Redshift cluster. For more information, see [Creating a Role to Delegate Permissions to an AWS Service](#) in the *IAM User Guide*.
- **Applications running on EC2 instances** – Instead of storing access keys on an EC2 instance for use by applications that run on the instance and make AWS API requests, you can use an IAM role to provide temporary access keys for these applications. To assign an IAM role to an EC2 instance, you create an *instance profile* and then attach it when you launch the instance. An instance profile contains the role and enables applications running on the EC2 instance to get temporary access keys. For more information, see [Using Roles for Applications on Amazon EC2](#) in the *IAM User Guide*.

## Access Control

You can have valid credentials to authenticate your requests, but you also need permissions to make AWS KMS API requests to create, manage, or use AWS KMS resources. For example, you must have permissions to create a KMS CMK, to manage the CMK, to use the CMK for cryptographic operations (such as encryption and decryption), and so on.

The following pages describe how to manage permissions for AWS KMS. We recommend that you read the overview first.

- [Overview of Managing Access](#) (p. 47)
- [Using Key Policies](#) (p. 50)
- [Using IAM Policies](#) (p. 67)
- [AWS KMS API Permissions Reference](#) (p. 76)
- [Using Policy Conditions](#) (p. 86)
- [Using Grants](#) (p. 115)
- [Using Service-Linked Roles](#) (p. 117)
- [Determining Access](#) (p. 118)

## Overview of Managing Access to Your AWS KMS Resources

Every AWS resource belongs to an AWS account, and permissions to create or access the resources are defined in permissions policies in that account. An account administrator can attach permissions policies

to IAM identities (that is, users, groups, and roles), and some services (including AWS KMS) also support attaching permissions policies to other kinds of resources.

**Note**

An *account administrator* (or administrator user) is a user with administrator permissions. For more information, see [Creating an Admin User and Group](#) in the *IAM User Guide*.

When managing permissions, you decide who gets the permissions, the resources they get permissions for, and the specific actions allowed.

**Topics**

- [AWS KMS Resources and Operations](#) (p. 48)
- [Managing Access to AWS KMS CMKs](#) (p. 48)
- [Specifying Permissions in a Policy](#) (p. 49)
- [Specifying Conditions in a Policy](#) (p. 50)

## AWS KMS Resources and Operations

To manage permissions, you should understand some basic information about resources and operations. In AWS KMS, the primary resource type is a *customer master key* (CMK). AWS KMS also supports another resource type you can use with CMKs: an *alias*. An alias is a friendly name that points to a CMK. Some AWS KMS operations allow you to specify a CMK by its alias.

These resource types have unique Amazon Resource Names (ARNs) associated with them, as shown in the following list.

- **Customer master key (CMK)**

ARN format:

`arn:AWS partition name:AWS Region:AWS account ID:key/CMK key ID`

Example ARN:

`arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`

- **Alias**

ARN format:

`arn:AWS partition name:AWS region:AWS account ID:alias/alias name`

Example ARN:

`arn:aws:kms:us-west-2:111122223333:alias/example-alias`

AWS KMS provides a set of API operations to work with your AWS KMS resources. For a list of available operations and the resources affected by each operation, see [AWS KMS API Permissions Reference](#) (p. 76).

## Managing Access to AWS KMS CMKs

The primary way to manage access to your AWS KMS CMKs is with *policies*. Policies are documents that describe who has access to what. Policies attached to an IAM identity are called *identity-based policies* (or

*IAM policies*), and policies attached to other kinds of resources are called *resource-based policies*. In AWS KMS, you must attach resource-based policies to your customer master keys (CMKs). These are called *key policies*. All KMS CMKs have a key policy.

You can control access to your KMS CMKs in these ways:

- **Use the key policy** – You must use the key policy to control access to a CMK. You can use the key policy alone to control access, which means the full scope of access to the CMK is defined in a single document (the key policy).
- **Use IAM policies in combination with the key policy** – You can use IAM policies in combination with the key policy to control access to a CMK. Controlling access this way enables you to manage all of the permissions for your IAM identities in IAM.
- **Use grants in combination with the key policy** – You can use grants in combination with the key policy to allow access to a CMK. Controlling access this way enables you to allow access to the CMK in the key policy, and to allow users to delegate their access to others.

For most AWS services, IAM policies are the only way to control access to the service's resources. Some services offer resource-based policies or other access control mechanisms to complement IAM policies, but these are generally optional and you can control access to the resources in these services with only IAM policies. This is not the case for AWS KMS, however. To allow access to a KMS CMK, you must use the key policy, either alone or in combination with IAM policies or grants. IAM policies by themselves are not sufficient to allow access to a CMK, though you can use them in combination with a CMK's key policy.

For more information about using key policies, see [Using Key Policies \(p. 50\)](#).

For more information about using IAM policies, see [Using IAM Policies \(p. 67\)](#).

For more information about using grants, see [Using Grants \(p. 115\)](#).

## Specifying Permissions in a Policy

AWS KMS provides a set of API operations. To control access to these API operations, AWS KMS provides a set of *actions* that you can specify in a policy. For more information, see [AWS KMS API Permissions Reference \(p. 76\)](#).

A policy is a document that describes a set of permissions. The following are the basic elements of a policy.

- **Resource** – In an IAM policy, you use an Amazon Resource Name (ARN) to specify the resource that the policy applies to. For more information, see [AWS KMS Resources and Operations \(p. 48\)](#). In a key policy, you use "\*" for the resource, which effectively means "this CMK." A key policy applies only to the CMK it is attached to.
- **Action** – You use actions to specify the API operations you want to allow or deny. For example, the `kms:Encrypt` action corresponds to the AWS KMS [Encrypt](#) operation.
- **Effect** – You use the effect to specify whether to allow or deny the permissions. If you don't explicitly allow access to a resource, access is implicitly denied. You can also explicitly deny access to a resource, which you might do to make sure that a user cannot access it, even when a different policy allows access.

- **Principal** – In an IAM policy, you don't specify a principal. Instead, the identity (the IAM user, group, or role) that the policy is attached to is the implicit principal. In a key policy, you must specify the principal (the identity) that the permissions apply to. You can specify AWS accounts (root), IAM users, IAM roles, and some AWS services as principals in a key policy. IAM groups are not valid principals in a key policy.

For more information, see [Using Key Policies \(p. 50\)](#) and [Using IAM Policies \(p. 67\)](#).

## Specifying Conditions in a Policy

You can use another policy element called the *condition* to specify the circumstances in which a policy takes effect. For example, you might want a policy statement to take effect only after a specific date. Or, you might want a policy statement to control access based on whether a specific value exists in the API request.

To specify conditions, you use predefined *condition keys*. Some condition keys apply generally to AWS, and some are specific to AWS KMS. For more information, see [Using Policy Conditions \(p. 86\)](#).

## Using Key Policies in AWS KMS

Key policies are the primary way to control access to customer master keys (CMKs) in AWS KMS. They are not the only way to control access, but you cannot control access without them. For more information, see [Managing Access to AWS KMS CMKs \(p. 48\)](#).

### Topics

- [Overview of Key Policies \(p. 50\)](#)
- [Default Key Policy \(p. 51\)](#)
- [Example Key Policy \(p. 58\)](#)

## Overview of Key Policies

A key policy is a document that uses [JSON \(JavaScript Object Notation\)](#) to specify permissions. You can work with these JSON documents directly, or you can use the AWS Management Console to work with them using a graphical interface called the *default view*. For more information about the console's default view for key policies, see [Default Key Policy \(p. 51\)](#) and [Changing a Key Policy \(p. 64\)](#).

A key policy document cannot exceed 32 KB (32,768 bytes). Key policy documents use the same JSON syntax as other permissions policies in AWS and have the following basic structure:

```
{
  "Version": "2012-10-17",
  "Statement": [{
    "Sid": "statement identifier",
    "Effect": "effect",
    "Principal": "principal",
    "Action": "action",
    "Resource": "resource",
    "Condition": { "condition operator": { "condition context key": "context key value" } }
  ]
}
```

```
}
```

A key policy document must have a `Version` element. We recommend setting the version to 2012-10-17 (the latest version). In addition, a key policy document must have one or more statements, and each statement consists of up to six elements:

- **Sid** – (Optional) The Sid is a statement identifier, an arbitrary string you can use to identify the statement.
- **Effect** – (Required) The effect specifies whether to allow or deny the permissions in the policy statement. The Effect must be Allow or Deny. If you don't explicitly allow access to a CMK, access is implicitly denied. You can also explicitly deny access to a CMK. You might do this to make sure that a user cannot access it, even when a different policy allows access.
- **Principal** – (Required) The [principal](#) is the identity that gets the permissions specified in the policy statement. You can specify AWS accounts (root), IAM users, IAM roles, and some AWS services as principals in a key policy. IAM groups are not valid principals.

#### Note

Do not set the Principal to an asterisk (\*) in any key policy statement that allows permissions. An asterisk gives every identity in every AWS account permission to use the CMK, unless another policy statement explicitly denies it. Users in other AWS accounts just need corresponding IAM permissions in their own accounts to use the CMK.

- **Action** – (Required) Actions specify the API operations to allow or deny. For example, the `kms:Encrypt` action corresponds to the AWS KMS [Encrypt](#) operation. You can list more than one action in a policy statement. For more information, see [AWS KMS API Permissions Reference](#) (p. 76).
- **Resource** – (Required) In a key policy, you use "\*" for the resource, which means "this CMK." A key policy applies only to the CMK it is attached to.
- **Condition** – (Optional) Conditions specify requirements that must be met for a key policy to take effect. With conditions, AWS can evaluate the context of an API request to determine whether or not the policy statement applies. For more information, see [Using Policy Conditions](#) (p. 86).

For more information about AWS policy syntax, see [AWS IAM Policy Reference](#) in the *IAM User Guide*.

## Default Key Policy

### Default key policy when you create a CMK programmatically

When you create a CMK programmatically—that is, with the [AWS KMS API](#) (including through the [AWS SDKs](#) and [command line tools](#))—you have the option of providing the key policy for the new CMK. If you don't provide one, AWS KMS creates one for you. This default key policy has one policy statement that gives the AWS account (root user) that owns the CMK full access to the CMK and enables IAM policies in the account to allow access to the CMK. For more information about this policy statement, see [Allows Access to the AWS Account and Enables IAM Policies](#) (p. 52).

### Default key policy when you create a CMK with the AWS Management Console

When you [create a CMK with the AWS Management Console](#) (p. 17), you can choose the IAM users, IAM roles, and AWS accounts that are given access to the CMK. The users, roles, and accounts that you choose are added to a default key policy that the console creates for you. With the console, you can use the default view to view or modify this key policy, or you can work with the key policy document directly. The default key policy created by the console allows the following permissions, each of which is explained in the corresponding section.

#### Permissions

- [Allows Access to the AWS Account and Enables IAM Policies](#) (p. 52)
- [Allows Key Administrators to Administer the CMK](#) (p. 52)

- [Allows Key Users to Use the CMK \(p. 54\)](#)
- [Allows Key Users to Use a CMK for Cryptographic Operations \(p. 56\)](#)
- [Allows Key Users to Use the CMK with AWS Services \(p. 57\)](#)

## Allows Access to the AWS Account and Enables IAM Policies

The default key policy gives the AWS account (root user) that owns the CMK full access to the CMK, which accomplishes the following two things.

### 1. Reduces the risk of the CMK becoming unmanageable.

You cannot delete your AWS account's root user, so allowing access to this user reduces the risk of the CMK becoming unmanageable. Consider this scenario:

1. A CMK's key policy allows *only* one IAM user, Alice, to manage the CMK. This key policy does not allow access to the root user.
2. Someone deletes IAM user Alice.

In this scenario, the CMK is now unmanageable, and you must [contact AWS Support](#) to regain access to the CMK. The root user does not have access to the CMK, because the root user can access a CMK only when the key policy explicitly allows it. This is different from most other resources in AWS, which implicitly allow access to the root user.

### 2. Enables IAM policies to allow access to the CMK.

IAM policies by themselves are not sufficient to allow access to a CMK. However, you can use them in combination with a CMK's key policy if the key policy enables it. Giving the AWS account full access to the CMK does this; it enables you to use IAM policies to give IAM users and roles in the account access to the CMK. It does not by itself give any IAM users or roles access to the CMK, but it enables you to use IAM policies to do so. For more information, see [Managing Access to AWS KMS CMKs \(p. 48\)](#).

The following example shows the policy statement that allows access to the AWS account and thereby enables IAM policies.

```
{
  "Sid": "Enable IAM User Permissions",
  "Effect": "Allow",
  "Principal": { "AWS": "arn:aws:iam::111122223333:root" },
  "Action": "kms:*",
  "Resource": "*"
}
```

## Allows Key Administrators to Administer the CMK

The default key policy created by the console allows you to choose IAM users and roles in the account and make them *key administrators*. Key administrators have permissions to manage the CMK, but do not have permissions to use the CMK in cryptographic operations.

### Warning

Even though key administrators do not have permissions to use the CMK to encrypt and decrypt data, they do have permission to change the key policy. This means they can give themselves any AWS KMS permission.

You can add IAM users and roles to the list of key administrators when you create the CMK. You can also edit the list with the console's default view for key policies, as shown in the following image. The default view for key policies is available on the key details page for each CMK.

Key policy
Tags

Key policy
Switch to policy view

### Key administrators

Choose the IAM users and roles who can administer this key through the KMS API. You might need to add additional permissions for the users or roles to administer this key from this console. [Learn more](#)

Add
Remove

< 1 >

<input type="checkbox"/>	Name	Path	Type
<input type="checkbox"/>	KMSAdminUser	/	User
<input type="checkbox"/>	KMSAdminRole	/	Role

### Key deletion

☒ Allow key administrators to delete this key

When you use the console's default view to modify the list of key administrators, the console modifies the **Principal** element in a particular statement in the key policy. This statement is called the *key administrators statement*. The following example shows the key administrators statement.

```
{
  "Sid": "Allow access for Key Administrators",
  "Effect": "Allow",
  "Principal": { "AWS": [
    "arn:aws:iam::111122223333:user/KMSAdminUser",
    "arn:aws:iam::111122223333:role/KMSAdminRole"
  ] },
  "Action": [
    "kms:Create*",
    "kms:Describe*",
    "kms:Enable*",
    "kms:List*",
    "kms:Put*",
    "kms:Update*",
    "kms:Revoke*",
    "kms:Disable*",
    "kms:Get*",
    "kms:Delete*",
    "kms:TagResource",
    "kms:UntagResource",
    "kms:ScheduleKeyDeletion",
    "kms:CancelKeyDeletion"
  ],
  "Resource": "*"
}
```

The key administrators statement allows the following permissions:

- **kms:Create\*** – Allows key administrators to create aliases and [grants \(p. 115\)](#) for this CMK.
- **kms:Describe\*** – Allows key administrators to get information about this CMK including its identifiers, creation date, state, and more. This permission is necessary to view the key details page in the AWS Management Console.
- **kms:Enable\*** – Allows key administrators to set this CMK's state to enabled. For symmetric CMKs, it allows key administrators to specify [annual rotation of the CMK's key material \(p. 142\)](#).
- **kms:List\*** – Allows key administrators to get lists of the aliases, grants, key policies, and tags for this CMK. This permission is necessary to view the list of CMKs in the AWS Management Console.
- **kms:Put\*** – Allows key administrators to change the key policy for this CMK.
- **kms:Update\*** – Allows key administrators to change the target of an alias to this CMK, and to change this CMK's description.
- **kms:Revoke\*** – Allows key administrators to revoke the permissions for this CMK that are allowed by a [grant \(p. 115\)](#).
- **kms:Disable\*** – Allows key administrators to set this CMK's key state to disabled. For symmetric CMKs, it allows key administrators to disable [annual rotation of this CMK's key material \(p. 142\)](#).
- **kms:Get\*** – Allows key administrators to get the key policy for this CMK and to determine whether this CMK's key material is rotated annually. For [symmetric CMKs \(p. 130\)](#) with [imported key material \(p. 147\)](#), it also allows key administrators to download the import token and public key that they need to import key material into the CMK. For [asymmetric CMKs \(p. 130\)](#), it allows key administrators to [download the public key \(p. 43\)](#) of the CMK.
- **kms>Delete\*** – Allows key administrators to delete an alias that points to this CMK. For symmetric CMKs with [imported key material \(p. 147\)](#), it lets the key administrator, delete the imported key material. Note that this permission does not allow key administrators to [delete the CMK \(p. 160\)](#).
- **kms:ImportKeyMaterial** – Allows key administrators to import key material into the CMK. This permission is included in the key policy only when you [create a CMK with no key material \(p. 150\)](#).

#### Note

This permission is not shown in the preceding example policy statement.

- **kms:TagResource** – Allows key administrators to add and update tags for this CMK.
- **kms:UntagResource** – Allows key administrators to remove tags from this CMK.
- **kms:ScheduleKeyDeletion** – Allows key administrators to [delete this CMK \(p. 160\)](#).
- **kms:CancelKeyDeletion** – Allows key administrators to cancel the pending deletion of this CMK.

The final two permissions in the preceding list, `kms:ScheduleKeyDeletion` and `kms:CancelKeyDeletion`, are included by default when you [create a CMK \(p. 17\)](#). However, you can optionally remove them from the key policy when you create a CMK by clearing the box for **Allow key administrators to delete this key**. In the same way, you can use the key details page to remove them from the default key policy for existing CMKs. For more information, see [Editing Keys \(p. 36\)](#).

Many of these permissions contain the wildcard character (\*). That means that if AWS KMS adds new API operations in the future, key administrators will automatically be allowed to perform all new API operations that begin with Create, Describe, Enable, List, Put, Update, Revoke, Disable, Get, or Delete.

#### Note

The key administrators statement described in the preceding section is in the latest version of the default key policy. For information about previous versions of the default key policy, see [Keeping Key Policies Up to Date \(p. 66\)](#).

## Allows Key Users to Use the CMK

The default key policy that the console creates for symmetric CMKs allows you to choose IAM users and roles in the account, and external AWS accounts, and make them *key users*.

The console adds two policy statements to the key policy for key users.

- [Use the CMK directly \(p. 56\)](#) — The first key policy statement gives key users have permission to use the CMK directly for all supported cryptographic operations for that type of CMK.
- [Use the CMK with AWS services \(p. 57\)](#) — The second policy statement gives key users permission to allow AWS services that are integrated with AWS KMS to use the CMK on their behalf to protect resources, such as [Amazon Simple Storage Service buckets \(p. 265\)](#) and [Amazon DynamoDB tables \(p. 233\)](#).

You can add IAM users, IAM roles, and other AWS accounts to the list of key users when you create the CMK. You can also edit the list with the console's default view for key policies, as shown in the following image. The default view for key policies is on the key details page. For more information about allowing users in other AWS accounts to use the CMK, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

### Key users

The following IAM users and roles can use this key for cryptographic operations. They can also allow AWS services that are integrated with KMS to use the key on their behalf. [Learn more](#)

}
```

## Allows Key Users to Use a CMK for Cryptographic Operations

Key users have permission to use the CMK directly in all cryptographic operations supported on the CMK. They can also use the [DescribeKey](#) operation to get detailed information about the CMK in the AWS KMS console or by using the AWS KMS API operations.

By default, the AWS KMS console adds key users statements like those in the following examples to the default key policy. Because they support different API operations, the actions in the policy statements for symmetric CMKs, asymmetric CMKs for public key encryption, and asymmetric CMKs for signing and verification are slightly different.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

### Symmetric CMKs

The console adds the following statement to the key policy for symmetric CMKs.

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/CMKUser"},
  "Action": [
    "kms:Decrypt",
    "kms:DescribeKey",
    "kms:Encrypt",
    "kms:GenerateDataKey*",
    "kms:ReEncrypt*"
  ],
  "Resource": "*"
}
```

### Asymmetric CMKs for Public Key Encryption

The console adds the following statement to the key policy for asymmetric CMKs with a key usage of **Encrypt and decrypt**.

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/CMKUser"},
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:DescribeKey",

```

```
        "kms:GetPublicKey"  
      ],  
      "Resource": "*"   
    }  
  }
```

### Asymmetric CMKs for Signing and Verification

The console adds the following statement to the key policy for asymmetric CMKs with a key usage of **Sign and verify**.

```
{  
  "Sid": "Allow use of the key",  
  "Effect": "Allow",  
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/CMKUser"},  
  "Action": [  
    "kms:DescribeKey",  
    "kms:GetPublicKey",  
    "kms:Sign",  
    "kms:Verify"  
  ],  
  "Resource": "*"   
}
```

The actions in these statements give the key users some of the following permissions.

- [kms:Encrypt](#) – Allows key users to encrypt data with this CMK.
- [kms:Decrypt](#) – Allows key users to decrypt data with this CMK.
- [kms:DescribeKey](#) – Allows key users to get detailed information about this CMK including its identifiers, creation date, and key state. It also allows the key users to display details about the CMK in the AWS KMS console.
- [kms:GenerateDataKey\\*](#) – Allows key users to request a symmetric data key or an asymmetric data key pair for client-side cryptographic operations. The console uses the \* wildcard character to represent permission for the following API operations: [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), [GenerateDataKeyPair](#), and [GenerateDataKeyPairWithoutPlaintext](#).
- [kms:GetPublicKey](#) – Allows key users to download the public key of the asymmetric CMK. Parties with whom you share this public key can encrypt data outside of AWS KMS. However, those ciphertexts can be decrypted only by calling the [Decrypt](#) operation in AWS KMS.
- [kms:ReEncrypt\\*](#) – Allows key users to re-encrypt data that was originally encrypted with this CMK, or to use this CMK to re-encrypt previously encrypted data. The [ReEncrypt](#) operation requires access to both source and destination CMKs. To accomplish this, you can allow the [kms:ReEncryptFrom](#) permission on the source CMK and [kms:ReEncryptTo](#) permission on the destination CMK. However, for simplicity, the console allows [kms:ReEncrypt\\*](#) (with the \* wildcard character) on both CMKs.
- [kms:Sign](#) – Allows key users to sign messages with this CMK.
- [kms:Verify](#) – Allows key users to verify signatures with this CMK.

## Allows Key Users to Use the CMK with AWS Services

The default key policy in the console also gives key users permission to allow [AWS services that are integrated with AWS KMS \(p. 228\)](#) to use the CMK, particularly services that use grants.

Key users can implicitly give these services permissions to use the CMK in specific and limited ways. This implicit delegation is done using [grants \(p. 115\)](#). These grants allow the integrated AWS service to use the CMK to protect resources in the account.

```
{
  "Sid": "Allow attachment of persistent resources",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/CMKUser"},
  "Action": [
    "kms:CreateGrant",
    "kms:ListGrants",
    "kms:RevokeGrant"
  ],
  "Resource": "*",
  "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
}
```

For example, key users can use these permissions on the CMK in the following ways.

- Use this CMK with Amazon Elastic Block Store (Amazon EBS) and Amazon Elastic Compute Cloud (Amazon EC2) to attach an encrypted EBS volume to an EC2 instance. The key user implicitly gives Amazon EC2 permission to use the CMK to attach the encrypted volume to the instance. For more information, see [How Amazon Elastic Block Store \(Amazon EBS\) Uses AWS KMS \(p. 243\)](#).
- Use this CMK with Amazon Redshift to launch an encrypted cluster. The key user implicitly gives Amazon Redshift permission to use the CMK to launch the encrypted cluster and create encrypted snapshots. For more information, see [How Amazon Redshift Uses AWS KMS \(p. 253\)](#).
- Use this CMK with other [AWS services integrated with AWS KMS \(p. 228\)](#), specifically the services that use grants, to create, manage, or use encrypted resources with those services.

The [kms:GrantIsForAWSResource \(p. 104\)](#) condition key allows key users to create and manage grants, but only when the grantee is an AWS service that uses grants. The permission allows key users to use *all* of the integrated services that use grants. However, you can create a custom key policy that allows particular AWS services to use the CMK on the key user's behalf. For more information, see the [kms:ViaService \(p. 111\)](#) condition key.

Key users need these grant permissions to use their CMK with integrated services, but these permissions are not sufficient. Key users also need permission to use the integrated services. For details about giving users access to an AWS service that integrates with AWS KMS, consult the documentation for the integrated service.

## Example Key Policy

The following example shows a complete key policy for a symmetric CMK. This key policy combines the example policy statements from the preceding [default key policy \(p. 51\)](#) section into a single key policy that accomplishes the following:

- Allows the AWS account (root user) 111122223333 full access to the CMK, and thus enables IAM policies in the account to allow access to the CMK.
- Allows IAM user KMSAdminUser and IAM role KMSAdminRole to administer the CMK.
- Allows IAM user CMKUser, IAM role CMKRole, and AWS account 444455556666 to use the CMK.

```
{
  "Version": "2012-10-17",
  "Id": "key-consolepolicy-2",
  "Statement": [
    {
      "Sid": "Enable IAM User Permissions",

      "Principal": {"AWS": "arn:aws:iam::111122223333:root"},
      "Action": "kms:*"
    }
  ]
}
```

```

    "Resource": "*"
  },
  {
    "Sid": "Allow access for Key Administrators",
    "Effect": "Allow",
    "Principal": { "AWS": [
      "arn:aws:iam::111122223333:user/KMSAdminUser",
      "arn:aws:iam::111122223333:role/KMSAdminRole"
    ] },
    "Action": [
      "kms:Create*",
      "kms:Describe*",
      "kms:Enable*",
      "kms:List*",
      "kms:Put*",
      "kms:Update*",
      "kms:Revoke*",
      "kms:Disable*",
      "kms:Get*",
      "kms>Delete*",
      "kms:TagResource",
      "kms:UntagResource",
      "kms:ScheduleKeyDeletion",
      "kms:CancelKeyDeletion"
    ],
    "Resource": "*"
  },
  {
    "Sid": "Allow use of the key",
    "Effect": "Allow",
    "Principal": { "AWS": [
      "arn:aws:iam::111122223333:user/CMKUser",
      "arn:aws:iam::111122223333:role/CMKRole",
      "arn:aws:iam::444455556666:root"
    ] },
    "Action": [
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:DescribeKey"
    ],
    "Resource": "*"
  },
  {
    "Sid": "Allow attachment of persistent resources",
    "Effect": "Allow",
    "Principal": { "AWS": [
      "arn:aws:iam::111122223333:user/CMKUser",
      "arn:aws:iam::111122223333:role/CMKRole",
      "arn:aws:iam::444455556666:root"
    ] },
    "Action": [
      "kms:CreateGrant",
      "kms:ListGrants",
      "kms:RevokeGrant"
    ],
    "Resource": "*",
    "Condition": { "Bool": { "kms:GrantIsForAWSResource": "true" } }
  }
]
}

```

The following image shows an example of what this key policy looks like when viewed with the console's default view for key policies.

## Viewing a Key Policy

You can view the key policy for an AWS KMS [customer managed CMK \(p. 3\)](#) or an [AWS managed CMK \(p. 4\)](#) in your account by using the AWS Management Console or the [GetKeyPolicy](#) operation in the AWS KMS API. You cannot use these techniques to view the key policy of a CMK in a different AWS account.

To learn more about AWS KMS key policies, see [Using Key Policies in AWS KMS \(p. 50\)](#). To learn how to determine which users and roles have access to a CMK, see [the section called “Determining Access” \(p. 118\)](#).

### Topics

- [Viewing a Key Policy \(Console\) \(p. 61\)](#)
- [Viewing a Key Policy \(KMS API\) \(p. 63\)](#)

## Viewing a Key Policy (Console)

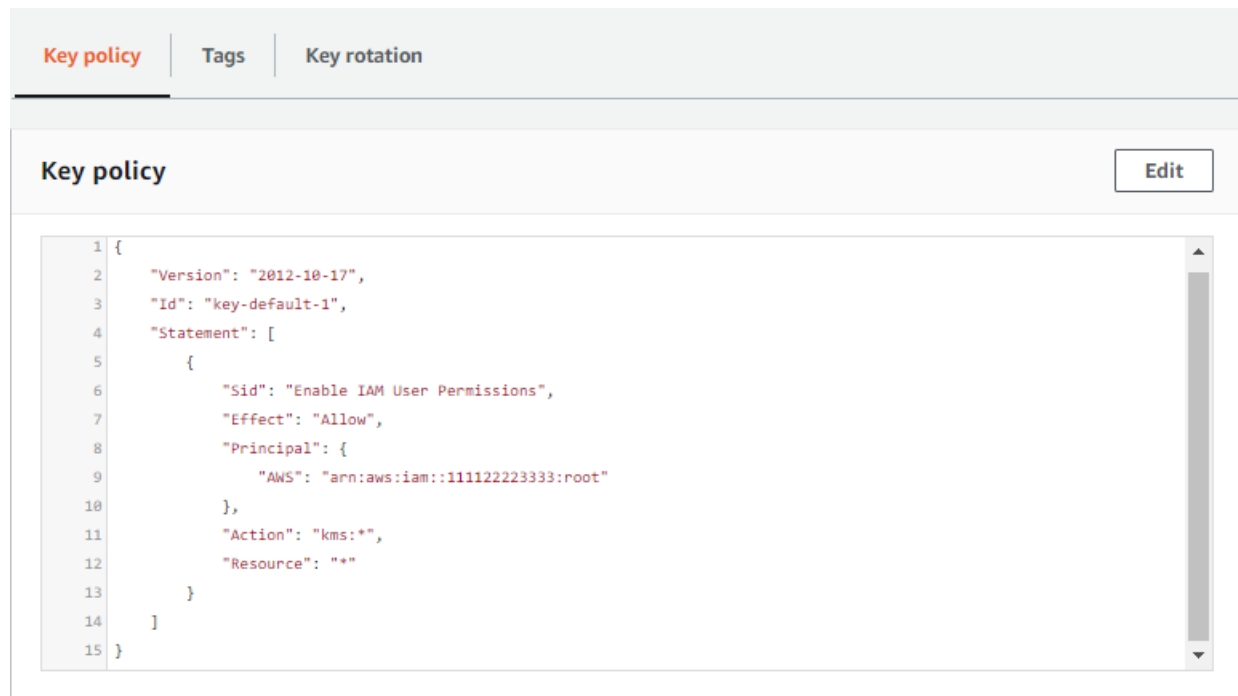

Authorized users can view the key policy for an [AWS managed CMK \(p. 4\)](#) or a [customer managed CMK \(p. 3\)](#) on the **Key policy** tab of the AWS Management Console.

To view the key policy for a CMK in the AWS Management Console, you must have [kms:ListAliases](#), [kms:DescribeKey](#), and [kms:GetKeyPolicy](#) permissions.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. To view the keys in your account that AWS creates and manages for you, in the navigation pane, choose **AWS managed keys**. To view the keys in your account that you create and manage, in the navigation pane choose **Customer managed keys**.
4. In the list of CMKs, choose the alias or key ID of the CMK that you want to examine.
5. Choose the **Key policy** tab.

In the **Key policy** section, you might see the key policy document. This is *policy view*. In the key policy statements, you can see the principals who have been given access to the CMK by the key policy, and you can see the actions they can perform.

The following example shows the policy view for the [default key policy \(p. 51\)](#).

Or, if you created the CMK in the AWS Management Console, you will see the *default view* with sections for **Key administrators**, **Key deletion**, and **Key Users**. To see the key policy document, choose **Switch to policy view**.

The following example shows the default view for the [default key policy \(p. 51\)](#).

## Viewing a Key Policy (KMS API)

To get the key policy for an [AWS managed CMK \(p. 4\)](#) or a [customer managed CMK \(p. 3\)](#) in your AWS account, use the [GetKeyPolicy](#) operation in the AWS KMS API. You cannot use this operation to view a key policy in a different account.

The following example uses the [get-key-policy](#) command in the AWS Command Line Interface (AWS CLI), but you can use any AWS SDK to make this request.

Note that the `PolicyName` parameter is required even though `default` is its only valid value. Also, this command requests the output in text, rather than JSON, to make it easier to view.

Before running this command, replace the example key ID with a valid one from your account.

```
$ aws kms get-key-policy --key-id 1234abcd-12ab-34cd-56ef-1234567890ab --policy-name default --output text
```

The response should be similar to the following one, which returns the [default key policy \(p. 51\)](#).

```
{
  "Version" : "2012-10-17",
  "Id" : "key-consolepolicy-3",
  "Statement" : [ {
    "Sid" : "Enable IAM User Permissions",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::111122223333:root"
    },
    "Action" : "kms:*",
    "Resource" : "*"
  } ]
}
```

## Changing a Key Policy

You can change the key policy for a customer master key (CMK) in your AWS account by using the AWS Management Console or the [PutKeyPolicy](#) operation. You cannot use these techniques to change the key policy of a CMK in a different AWS account.

When changing a key policy, keep in mind the following rules:

- You can view the key policy for an [AWS managed CMK \(p. 4\)](#) or a [customer managed CMK \(p. 3\)](#), but you can only change the key policy for a customer managed CMK. The policies of AWS managed CMKs are created and managed by the AWS service that created the CMK in your account.
- You can add or remove IAM users, IAM roles, and AWS accounts (root users) in the key policy, and change the actions that are allowed or denied for those principals. For more information about the ways to specify principals and permissions in a key policy, see [Using Key Policies \(p. 50\)](#).
- You cannot add IAM groups to a key policy, but you can add multiple IAM users. For more information, see [Allowing Multiple IAM Users to Access a CMK \(p. 66\)](#).
- If you add external AWS accounts to a key policy, you must also use IAM policies in the external accounts to give permissions to IAM users, groups, or roles in those accounts. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).
- The resulting key policy document cannot exceed 32 KB (32,768 bytes).

### Topics

- [How to Change a Key Policy \(p. 65\)](#)
- [Allowing Multiple IAM Users to Access a CMK \(p. 66\)](#)

## How to Change a Key Policy

You can change a key policy in three different ways, each of which is explained in the following sections.

### Topics

- [Using the AWS Management Console Default View](#) (p. 65)
- [Using the AWS Management Console Policy View](#) (p. 65)
- [Using the AWS KMS API](#) (p. 65)

### Using the AWS Management Console Default View

You can use the console to change a key policy with a graphical interface called the *default view*.

If the following steps don't match what you see in the console, it might mean that this key policy was not created by the console. Or it might mean that the key policy has been modified in a way that the console's default view does not support. In that case, follow the steps at [Using the AWS Management Console Policy View](#) (p. 65) or [Using the AWS KMS API](#) (p. 65).

1. View the key policy for a customer managed CMK as described in [Viewing a Key Policy \(Console\)](#) (p. 61). (You cannot change the key policies of AWS managed keys.)
2. Decide what to change.
  - To add or remove [key administrators](#) (p. 52), and to allow or prevent key administrators from [deleting the CMK](#) (p. 160), use the controls in the **Key administrators** section of the page. Key administrators manage the CMK, including enabling and disabling it, setting key policy, and [enabling key rotation](#) (p. 142).
  - To add or remove [key users](#) (p. 54), and to allow or disallow external AWS accounts to use the CMK, use the controls in the **Key users** section of the page. Key users can use the CMK in cryptographic operations, such as encrypting, decrypting, re-encrypting, and generating data keys.

### Using the AWS Management Console Policy View

You can use the console to change a key policy document with the console's *policy view*.

1. View the key policy for a customer managed CMK as described in [Viewing a Key Policy \(Console\)](#) (p. 61). (You cannot change the key policies of AWS managed keys.)
2. In the **Key Policy** section, choose **Switch to policy view**.
3. Edit the key policy document, and then choose **Save changes**.

### Using the AWS KMS API

You can use the [PutKeyPolicy](#) operation to change the key policy of a CMK in your AWS account. You cannot use this API on a CMK in a different AWS account.

1. Use the [GetKeyPolicy](#) operation to get the existing key policy document, and then save the key policy document to a file. For sample code in multiple programming languages, see [Getting a Key Policy](#) (p. 332).
2. Open the key policy document in your preferred text editor, edit the key policy document, and then save the file.
3. Use the [PutKeyPolicy](#) operation to apply the updated key policy document to the CMK. For sample code in multiple programming languages, see [Setting a Key Policy](#) (p. 334).

For an example of copying a key policy from one CMK to another, see the [GetKeyPolicy example](#) in the AWS CLI Command Reference.

## Allowing Multiple IAM Users to Access a CMK

IAM groups are not valid principals in a key policy. To allow multiple IAM users to access a CMK, do one of the following:

- Add each IAM user to the key policy. This approach requires that you update the key policy each time the list of authorized users changes.
- Ensure that the key policy includes the statement that [enables IAM policies to allow access to the CMK \(p. 52\)](#). Then [create an IAM policy](#) that allows access to the CMK, and then [attach that policy to an IAM group](#) that contains the authorized IAM users. Using this approach, you don't need to change any policies when the list of authorized users changes. Instead, you only need to add or remove those users from the appropriate IAM group.

For more information about how AWS KMS key policies and IAM policies work together, see [Troubleshooting Key Access \(p. 123\)](#).

## Keeping Key Policies Up to Date

When you [use the AWS Management Console to create a customer master key \(CMK\) \(p. 17\)](#), you can choose the IAM users, IAM roles, and AWS accounts that you want to have access to the CMK. These users, roles, and accounts are added to a [default key policy \(p. 51\)](#) that controls access to the CMK. Occasionally, the default key policy for new CMKs is updated. Typically, these updates correspond to new AWS KMS features.

When you create a new CMK, the latest version of the default key policy is added to the CMK. However, existing CMKs continue to use their existing key policy—that is, new versions of the default key policy are *not* automatically applied to existing CMKs. Instead, the console alerts you that a newer version is available and prompts you to upgrade it.

### Note

The console alerts you only when you are using the default key policy that was applied when you created the CMK. If you manually modified the key policy document using the console's *policy view* or the [PutKeyPolicy](#) operation, the console does not alert you when new permissions are available.

For information about the permissions that are added to a key policy when you upgrade it, see [Changes to the Default Key Policy \(p. 67\)](#). Upgrading to the latest version of the key policy should not cause problems because it only adds permissions; it doesn't remove any. We recommend keeping your key policies up to date unless you have a specific reason not to.

## Determining whether a newer version of the default key policy is available

You can use the AWS Management Console to learn whether a newer version of the default key policy is available.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose the alias or key ID of a CMK that uses the default key policy.

5. Scroll down to the **Key policy** section of the page.

When a newer version of the default key policy is available, the console displays the following alert.

**A newer version of the default key policy is available. Preview and upgrade to the new key policy.**

## Upgrading to the latest version of the default key policy

When a new default key policy is available, the following alert is displayed in the Key Policy section of the console page.

**A newer version of the default key policy is available. Preview and upgrade to the new key policy.**

### To upgrade to the latest version of the default key policy

1. If you see an alert announcing a newer version of the default key policy, choose **Preview and upgrade to the new key policy**.
2. Review the key policy document for the latest version of the default key policy. For more information about the difference between the latest version and previous versions, see [Changes to the Default Key Policy \(p. 67\)](#). After reviewing the key policy, choose **Upgrade key policy**.

## Changes to the Default Key Policy

In the [current version of the default key policy \(p. 51\)](#), the *key administrators statement* contains more permissions than those in previous versions. These additional permissions correspond to new AWS KMS features.

CMKs that use an earlier version of the default key policy might be missing the following permissions. When you upgrade to the latest version of the default key policy, they're added to the key administrators statement.

### **kms:TagResource and kms:UntagResource**

These permissions allow key administrators to add, update, and remove tags from the CMK. They were added to the default key policy when AWS KMS released the [tagging feature \(p. 39\)](#).

### **kms:ScheduleKeyDeletion and kms:CancelKeyDeletion**

These permissions allow key administrators to schedule and cancel deletion for the CMK. They were added to the default key policy when AWS KMS released the [CMK deletion feature \(p. 160\)](#).

#### **Note**

The `kms:ScheduleKeyDeletion` and `kms:CancelKeyDeletion` permissions are included by default when you [create a CMK \(p. 17\)](#) and when you upgrade to the latest version of the default key policy. However, you can optionally remove them from the default key policy when you create a CMK by clearing the box for **Allow key administrators to delete this key**. In the same way, you can use the key details page to remove them from the default key policy for existing CMKs. That includes CMKs whose key policy you upgraded to the latest version.

## Using IAM Policies with AWS KMS

You can use IAM policies in combination with [key policies \(p. 50\)](#) to control access to your customer master keys (CMKs) in AWS KMS.

### Note

This section discusses using IAM in the context of AWS KMS. It doesn't provide detailed information about the IAM service. For complete IAM documentation, see the [IAM User Guide](#).

Policies attached to IAM identities (that is, users, groups, and roles) are called *identity-based policies* (or *IAM policies*), and policies attached to resources outside of IAM are called *resource-based policies*. In AWS KMS, you must attach resource-based policies to your CMKs. These are called *key policies*. All KMS CMKs have a key policy, and you must use it to control access to a CMK. IAM policies by themselves are not sufficient to allow access to a CMK, though you can use them in combination with a CMK's key policy. To do so, ensure that CMK's key policy includes the [policy statement that enables IAM policies](#) (p. 52).

### Topics

- [Overview of IAM Policies](#) (p. 68)
- [Permissions Required to Use the AWS KMS Console](#) (p. 68)
- [AWS Managed \(Predefined\) Policies for AWS KMS](#) (p. 69)
- [Customer Managed Policy Examples](#) (p. 69)

## Overview of IAM Policies

You can use IAM policies in the following ways:

- **Attach a permissions policy to a user or a group** – You can attach a policy that allows an IAM user or group of users to, for example, create new CMKs.
- **Attach a permissions policy to a role for federation or cross-account permissions** – You can attach an IAM policy to an IAM role to enable identity federation, allow cross-account permissions, or give permissions to applications running on EC2 instances. For more information about the various use cases for IAM roles, see [IAM Roles](#) in the *IAM User Guide*.

The following example shows an IAM policy with AWS KMS permissions. This policy allows the IAM identities to which it is attached to retrieve a list of all CMKs and aliases.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:ListKeys",
      "kms:ListAliases"
    ],
    "Resource": "*"
  }
}
```

This policy doesn't specify the `Principal` element because in IAM policies you don't specify the principal who gets the permissions. When you attach this policy to an IAM user, that user is the implicit principal. When you attach this policy to an IAM role, the *assumed role user* gets the permissions.

For a table showing all of the AWS KMS API actions and the resources that they apply to, see the [AWS KMS API Permissions Reference](#) (p. 76).

## Permissions Required to Use the AWS KMS Console

To work with the AWS KMS console, users must have a minimum set of permissions that allow them to work with the AWS KMS resources in their AWS account. In addition to these AWS KMS permissions, users must also have permissions to list IAM users and roles. If you create an IAM policy that is more restrictive

than the minimum required permissions, the AWS KMS console won't function as intended for users with that IAM policy.

For the minimum permissions required to allow a user read-only access to the AWS KMS console, see [Allow a User Read-Only Access to All CMKs through the AWS KMS Console \(p. 69\)](#).

To allow users to work with the AWS KMS console to create and manage CMKs, attach the **AWSKeyManagementServicePowerUser** managed policy to the user, as described in the following section.

You don't need to allow minimum console permissions for users that are working with the AWS KMS API through the [AWS SDKs](#) or [command line tools](#), though you do need to grant these users permission to use the API. For more information, see [AWS KMS API Permissions Reference \(p. 76\)](#).

## AWS Managed (Predefined) Policies for AWS KMS

AWS addresses many common use cases by providing standalone IAM policies that are created and managed by AWS. These are called *AWS managed policies*. AWS managed policies provide the necessary permissions for common use cases so you don't have to investigate which permissions are needed. For more information, see [AWS Managed Policies](#) in the *IAM User Guide*.

AWS provides one AWS managed policy for AWS KMS called **AWSKeyManagementServicePowerUser**. This policy allows the following permissions:

- Allows users to list all CMKs and aliases.
- Allows users to retrieve information about each CMK, including its identifiers, creation date, rotation status, key policy, and more.
- Allows users to create CMKs that they can administer or use. When users create a CMK, they can set permissions in the CMK's [key policy \(p. 50\)](#). This means users can create CMKs with any permissions they want, including allowing themselves to administer or use the CMK. The **AWSKeyManagementServicePowerUser** policy does not allow users to administer or use any other CMKs, only the ones they create.

## Customer Managed Policy Examples

In this section, you can find example IAM policies that allow permissions for various AWS KMS actions.

### Important

Some of the permissions in the following policies are allowed only when the CMK's key policy also allows them. For more information, see [AWS KMS API Permissions Reference \(p. 76\)](#).

### Examples

- [Allow a User Read-Only Access to All CMKs through the AWS KMS Console \(p. 69\)](#)
- [Allow a User to Encrypt and Decrypt with Any CMK in a Specific AWS Account \(p. 70\)](#)
- [Allow a User to Encrypt and Decrypt with Any CMK in a Specific AWS Account and Region \(p. 70\)](#)
- [Allow a User to Encrypt and Decrypt with Specific CMKs \(p. 71\)](#)
- [Prevent a User from Disabling or Deleting Any CMKs \(p. 71\)](#)

## Allow a User Read-Only Access to All CMKs through the AWS KMS Console

The following policy allows users read-only access to the AWS KMS console. That is, users can use the console to view all CMKs, but they cannot make changes to any CMKs or create new ones.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:DescribeKey",
      "kms:GetKeyPolicy",
      "kms:GetKeyRotationStatus",
      "kms:GetPublicKey",
      "kms:ListKeys",
      "kms:ListAliases",
      "kms:ListKeyPolicies",
      "iam:ListUsers",
      "iam:ListRoles"
    ],
    "Resource": "*"
  }
}
```

## Allow a User to Encrypt and Decrypt with Any CMK in a Specific AWS Account

The following policy allows a user to successfully request that AWS KMS encrypt and decrypt data with any CMK in AWS account 11112223333.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Encrypt",
      "kms:Decrypt"
    ],
    "Resource": [
      "arn:aws:kms*:11112223333:key/*"
    ]
  }
}
```

## Allow a User to Encrypt and Decrypt with Any CMK in a Specific AWS Account and Region

The following policy allows a user to successfully request that AWS KMS encrypt and decrypt data with any CMK in AWS account 11112223333 in the US West (Oregon) region.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Encrypt",
      "kms:Decrypt"
    ],
    "Resource": [
      "arn:aws:kms:us-west-2:11112223333:key/*"
    ]
  }
}
```

## Allow a User to Encrypt and Decrypt with Specific CMKs

The following policy allows a user to successfully request that AWS KMS encrypt and decrypt data with the two CMKs specified in the policy's `Resource` element.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": [
      "kms:Encrypt",
      "kms:Decrypt"
    ],
    "Resource": [
      "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "arn:aws:kms:us-west-2:111122223333:key/0987dcb4-09fe-87dc-65ba-ab0987654321"
    ]
  }
}
```

## Prevent a User from Disabling or Deleting Any CMKs

The following policy prevents a user from disabling or deleting any CMKs, even when another IAM policy or a key policy allows these permissions. A policy that explicitly denies permissions overrides all other policies, even those that explicitly allow the same permissions. For more information, see [Determining Whether a Request is Allowed or Denied](#) in the *IAM User Guide*.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": [
      "kms:DisableKey",
      "kms:ScheduleKeyDeletion"
    ],
    "Resource": "*"
  }
}
```

## Allowing Users in Other Accounts to Use a CMK

You can allow IAM users or roles in one AWS account to use a customer master key (CMK) in a different AWS account. You can add these permissions when you create the CMK or change the permissions for an existing CMK.

To give permission to use a CMK to users and roles in another account, you must use two different types of policies:

- The **key policy** for the CMK must give the external account (or users and roles in the external account) permission to use the CMK. The key policy is in the account that owns the CMK.
- You must attach **IAM policies** to IAM users and roles in the external account. These IAM policies delegate the permissions that are specified in the key policy.

In this scenario, the key policy determines who *can* have access to the CMK. The IAM policy determines who *does* have access to the CMK. Neither the key policy nor the IAM policy alone is sufficient—you must change both.

To edit the key policy, you can use the [Policy View \(p. 65\)](#) in the AWS Management Console or use the [CreateKey](#) or [PutKeyPolicy](#) operations. For help setting the key policy when creating a CMK, see [Creating CMKs that Other Accounts Can Use \(p. 74\)](#).

For help with editing IAM policies, see [Using IAM Policies with AWS KMS \(p. 67\)](#).

For an example that shows how the key policy and IAM policies work together to allow use of a CMK in a different account, see [Example 2: User Assumes Role with Permission to Use a CMK in a Different AWS Account \(p. 125\)](#).

#### Topics

- [Step 1: Add a Key Policy Statement in the Local Account \(p. 72\)](#)
- [Step 2: Add IAM Policies in the External Account \(p. 73\)](#)
- [Creating CMKs that Other Accounts Can Use \(p. 74\)](#)
- [Using External CMKs with AWS Services \(p. 76\)](#)

## Step 1: Add a Key Policy Statement in the Local Account

The key policy for a CMK is the primary determinant of who can access the CMK and which operations they can perform. The key policy is always in the account that owns the CMK. Unlike IAM policies, key policies do not specify a resource. The resource is the CMK that is associated with the key policy.

To give an external account permission to use the CMK, add a statement to the key policy that specifies the external account. In the `Principal` element of the key policy, enter the Amazon Resource Name (ARN) of the external account.

When you specify an external account in a key policy, IAM administrators in the external account can use IAM policies to delegate those permissions to any users and roles in the external account. They can also decide which of the actions specified in the key policy the users and roles can perform.

For example, assume that you want to allow account 444455556666 to use a symmetric CMK in account 111122223333. To do that, add a policy statement like the one in the following example to the key policy for the CMK in account 111122223333. This policy statement gives the external account, 444455556666, permission to use the CMK in cryptographic operations for symmetric CMKs.

```
{
  "Sid": "Allow an external account to use this CMK",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:iam::444455556666:root"
    ]
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```

Instead of giving permission to the external account, you can specify particular external users and roles in the key policy. However, those users and roles cannot use the CMK until IAM administrators in the

external account attach the proper IAM policies to their identities. The IAM policies can give permission to all or a subset of the external users and roles that are specified in the key policy. And they can allow all or a subset of the actions specified in the key policy.

Specifying identities in a key policy restricts the permissions that IAM administrators in the external account can provide. However, it makes policy management with two accounts more complex. For example, assume that you need to add a user or role. You must add that identity to the key policy in the account that owns the CMK and create IAM policies in the identity's account.

To specify particular external users or roles in a key policy, in the `Principal` element, enter the Amazon Resource Name (ARN) of a user or role in the external account.

For example, the following example key policy statement allows `ExampleRole` and `ExampleUser` in account 444455556666 to use a CMK in account 111122223333. This key policy statement gives the external account, 444455556666, permission to use the CMK in cryptographic operations for symmetric CMKs.

```
{
  "Sid": "Allow an external account to use this CMK",
  "Effect": "Allow",
  "Principal": {
    "AWS": [
      "arn:aws:iam::444455556666:role/ExampleRole",
      "arn:aws:iam::444455556666:user/ExampleUser"
    ]
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```

#### Note

Do not set the `Principal` to an asterisk (\*) in any key policy statement that allows permissions. An asterisk gives every identity in every AWS account permission to use the CMK, unless another policy statement explicitly denies it. Users in other AWS accounts just need corresponding IAM permissions in their own accounts to use the CMK.

You also need to decide which permissions you want to give to the external account. For a list of permissions on CMKs, see [AWS KMS API Permissions: Actions and Resources Reference \(p. 76\)](#).

You can give the external account permission to use the CMK in cryptographic operations and use the CMK with AWS services that are integrated with AWS KMS. To do that, use the **Key Users** section of the AWS Management Console. For details, see [Creating CMKs that Other Accounts Can Use \(p. 74\)](#).

To specify other permissions in key policies, edit the key policy document. For example, you might want to give users permission to decrypt but not encrypt, or permission to view the CMK but not use it. To edit the key policy document, you can use the [Policy View \(p. 65\)](#) in the AWS Management Console or the [CreateKey](#) or [PutKeyPolicy](#) operations.

## Step 2: Add IAM Policies in the External Account

The key policy in the account that owns the CMK sets the valid range for permissions. But, users and roles in the external account cannot use the CMK until you attach IAM policies that delegate those permissions, or use grants to manage access to the CMK. The IAM policies are set in the external account.

If the key policy gives permission to the external account, you can attach IAM policies to any user or role in the account. But if the key policy gives permission to specified users or roles, the IAM policy can only give those permissions to all or a subset of the specified users and roles. If an IAM policy gives CMK access to other external users or roles, it has no effect.

The key policy also limits the actions in the IAM policy. The IAM policy can delegate all or a subset of the actions specified in the key policy. If the IAM policy lists actions that are not specified in the key policy, those permissions are not effective.

The following example IAM policy allows the principal to use the CMK in account 111122223333 for cryptographic operations. To give this permission to users and roles in account 444455556666, [attach the policy](#) to the users or roles in account 444455556666.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Allow Use Of CMK In Account 111122223333",
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncrypt*",
        "kms:GenerateDataKey*",
        "kms:DescribeKey"
      ],
      "Resource": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
  ]
}
```

Note the following details about this policy:

- Unlike key policies, IAM policy statements do not contain the `Principal` element. In IAM policies, the principal is the identity to which the policy is attached.
- The `Resource` element in the IAM policy identifies the CMK that the principal can use. To specify a CMK, add its [Amazon Resource Name \(ARN\)](#) (p. 48) to the `Resource` element. You can specify more than one CMK in the policy statement. But if you don't specify particular CMKs in the `Resource` element, you might inadvertently give access to more CMKs than you intend.
- To allow the external user to use the CMK with [AWS services that integrate with AWS KMS](#), you might need to add permissions to the key policy or the IAM policy. For details, see [Using External CMKs with AWS Services](#) (p. 76).

For more information about working with IAM policies, see [Using IAM Policies](#) (p. 67).

## Creating CMKs that Other Accounts Can Use

When you use the [CreateKey](#) operation to create a CMK, you can use its `Policy` parameter to specify a [key policy](#) (p. 72) that gives an external account, or external users and roles, permission to use the CMK. You must also add [IAM policies](#) (p. 73) in the external account that delegate these permissions to the account's users and roles, even when users and roles are specified in the key policy. You can change the key policy at any time by using the [PutKeyPolicy](#) operation.

When you create a CMK in the AWS Management Console, you also create its key policy. When you select identities in the **Key Administrators** and **Key Users** sections, AWS KMS adds policy statements for those identities to the CMK's key policy.

The **Key Users** section also lets you add external accounts as key users.

**Other AWS accounts**

Specify the AWS accounts that can use this key. Administrators of the accounts you specify are responsible for managing the permissions that allow their IAM users and roles to use this key. [Learn more](#)

arn:aws:iam::  :root Remove

Add another AWS account

When you enter the account ID of an external account, AWS KMS adds two statements to the key policy. This action only affects the key policy. Users and roles in the external account cannot use the CMK until you attach [IAM policies \(p. 73\)](#) to give them some or all of these permissions.

The first policy statement gives the external account permission to use the CMK in cryptographic operations.

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::444455556666:root"
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```

The second policy statement allows the external account to create, view, and revoke grants on the CMK, but only when the request comes from an [AWS service that is integrated with AWS KMS](#). These permissions allow other AWS services, such as that encrypt user data to use the CMK.

These permissions are designed for CMKs that encrypt user data in AWS services, such as [Amazon WorkMail \(p. 276\)](#). These services typically use grants to get the permissions they need to use the CMK on the user's behalf. For details, see [Using External CMKs with AWS Services \(p. 76\)](#).

```
{
  "Sid": "Allow attachment of persistent resources",
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::444455556666:root"
  },
  "Action": [
    "kms:CreateGrant",
    "kms:ListGrants",
    "kms:RevokeGrant"
  ],
  "Resource": "*",
  "Condition": {
    "Bool": {
      "kms:GrantIsForAWSResource": "true"
    }
  }
}
```

If these permissions don't meet your needs, you can edit them in the console [policy view \(p. 65\)](#) or by using the [PutKeyPolicy](#) operation. You can specify particular external users and role instead of giving permission to the external account. You can change the actions that the policy specifies. And you can use global and AWS KMS policy conditions to refine the permissions.

## Using External CMKs with AWS Services

You can give a user in a different account permission to use your CMK with a service that is integrated with AWS KMS. For example, a user in an external account can use your CMK to [encrypt the objects in an Amazon S3 bucket \(p. 265\)](#) or to [encrypt the secrets they store in AWS Secrets Manager \(p. 255\)](#).

The key policy must give the external user or the external user's account permission to use the CMK. In addition, you need to attach IAM policies to the identity that gives the user permission to use the AWS service.

Also, the service might require that users have additional permissions in the key policy. For example, it might require permission to create, list, and revoke grants on the CMK. Or it might require particular IAM policies. For details, see the documentation for the service.

Finally, the lists of CMKs displayed in the AWS Management Console for an integrated service do not include CMKs in external accounts. This is true even when the user or role has permission to use them. To use an external account's CMK, the user must enter the ID or ARN of the CMK. For details, see the service's console documentation.

## AWS KMS API Permissions: Actions and Resources Reference

The Actions and Resources Table is designed to help you define [access control \(p. 47\)](#) in [key policies \(p. 50\)](#) and [IAM policies \(p. 67\)](#). The columns provide the following information:

- **API Operations and Actions (Permissions)** lists each AWS KMS API operation and the corresponding action (permission) that allows the operation. You specify actions in a policy's `Action` element.
- **Policy Type** indicates whether the permission can be used in a key policy or IAM policy. When the type is *key policy*, you can specify the permission explicitly in the key policy. Or, if the key policy contains the [policy statement that enables IAM policies \(p. 52\)](#), you can specify the permission in an IAM policy. When the type is *IAM policy*, you can specify the permission only in an IAM policy.
- **Resources** lists the resources for which you can allow the operation. To specify a resource in an IAM policy, type the Amazon Resource Name (ARN) in the `Resource` element. Because a key policy applies only to the CMK that it is attached to, the value of its `Resource` element is always `"*"`.

Each resource type is associated with an ARN that you use to represent the resource.

### CMK ARNs

When the resource is a CMK, you represent it by using a CMK ARN.

`arn:AWS_partition_name:AWS_Region:AWS_account_ID:key/CMK_key_ID`

For example:

`arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`

### Alias ARNs

When the resource is an alias, you represent it by using an alias ARN.

`arn:AWS_partition_name:AWS_region:AWS_account_ID:alias/alias_name`

For example:

arn:aws:kms:us-west-2:11112223333:alias/ExampleAlias

- **AWS KMS Condition Keys** lists the AWS KMS condition keys that you can use to control access to the operation. You specify conditions in a policy's `Condition` element. For more information, see [AWS KMS Condition Keys \(p. 88\)](#). This column also includes [AWS global condition keys](#) that are supported by AWS KMS, but not by all AWS services.

## AWS KMS API Operations and Permissions

API Operations and Actions (Permissions)	Policy Type	Resources (for IAM Policies)	AWS KMS Condition Keys
<a href="#">CancelKeyDeletion</a>  <code>kms:CancelKeyDeletion</code>	Key policy	CMK	<code>kms:CallerAccount</code>  <code>kms:CustomerMasterKeySpec</code>  <code>kms:CustomerMasterKeyUsage</code>  <code>kms:KeyOrigin</code>  <code>kms:ViaService</code>

## Using Policy Conditions with AWS KMS

You can specify conditions in the key policies and AWS Identity and Access Management policies ([IAM policies \(p. 67\)](#)) that control access to AWS KMS resources. The policy statement is effective only when the conditions are true. For example, you might want a policy statement to take effect only after a specific date. Or, you might want a policy statement to control access only when a specific value appears in an API request.

To specify conditions, you use predefined *condition keys* in the `Condition` element of a policy statement with [IAM condition policy operators](#). Some condition keys apply generally to AWS; others are specific to AWS KMS.

### Topics

- [AWS Global Condition Keys \(p. 86\)](#)
- [AWS KMS Condition Keys \(p. 88\)](#)

## AWS Global Condition Keys

AWS provides [global condition keys](#), a set of predefined condition keys for all AWS services that use IAM for access control. For example, you can use the `aws:PrincipalArn` condition key to allow access only when the principal in the request is represented by the Amazon Resource Name (ARN) that you specify.

In addition to global conditions keys that are supported by every AWS service, IAM defines conditions keys that AWS services can choose to support. AWS KMS supports the following optional global condition keys.

- `aws:PrincipalTag`
- `aws:PrincipalType`

- `aws:RequestTag`
- `aws:SourceIp` (see [the section called “Using the IP Address Condition”](#) (p. 87))
- `aws:SourceVpc` (see [the section called “Using VPC and VPC Endpoint Conditions”](#) (p. 87))
- `aws:SourceVpce` (see [the section called “Using VPC and VPC Endpoint Conditions”](#) (p. 87))
- `aws:TagKeys`
- `aws:TokenIssueTime`
- `aws:userid`
- `aws:username`

For a list and descriptions of all optional global condition keys, see [Keys Available for Some Services](#) in the *AWS Identity and Access Management User Guide*. For examples of using these condition keys in IAM policies, see [Controlling Access to Requests](#) and [Controlling Tag Keys](#) in the *IAM User Guide*.

#### Topics

- [Using the IP Address Condition in Policies with AWS KMS Permissions](#) (p. 87)
- [Using VPC Endpoint Conditions in Policies with AWS KMS Permissions](#) (p. 87)

## Using the IP Address Condition in Policies with AWS KMS Permissions

You can use AWS KMS to protect your data in an [integrated AWS service](#) (p. 228). But use caution when specifying the [IP address condition operators](#) or the `aws:SourceIp` condition key in the same policy statement that allows or denies access to AWS KMS. For example, the policy in [AWS: Denies Access to AWS Based on the Source IP](#) restricts AWS actions to requests from the specified IP range.

Consider this scenario:

1. You attach a policy like the one shown at [AWS: Denies Access to AWS Based on the Source IP](#) to an IAM user. You set the value of the `aws:SourceIp` condition key to the range of IP addresses for the user's company. This IAM user has other policies attached that allow it to use Amazon EBS, Amazon EC2, and AWS KMS.
2. The user attempts to attach an encrypted EBS volume to an EC2 instance. This action fails with an authorization error even though the user has permission to use all the relevant services.

Step 2 fails because the request to AWS KMS to decrypt the volume's encrypted data key comes from an IP address that is associated with the Amazon EC2 infrastructure. To succeed, the request must come from the IP address of the originating user. Because the policy in step 1 explicitly denies all requests from IP addresses other than those specified, Amazon EC2 is denied permission to decrypt the EBS volume's encrypted data key.

Also, the `aws:sourceIP` condition key is not effective when the request comes from an [Amazon VPC endpoint](#). To restrict requests to a VPC endpoint, including an [AWS KMS VPC endpoint](#) (p. 211), use the `aws:sourceVpce` or `aws:sourceVpc` condition keys. For more information, see [VPC Endpoints - Controlling the Use of Endpoints](#) in the *Amazon VPC User Guide*.

## Using VPC Endpoint Conditions in Policies with AWS KMS Permissions

AWS KMS supports Amazon Virtual Private Cloud (Amazon VPC) endpoints (p. 211) that are powered by [AWS PrivateLink](#). You can use the following [global condition keys](#) in IAM policies to allow or deny access to a particular VPC or VPC endpoint. You can also use these global condition keys in [AWS KMS key policies](#) (p. 215) to restrict access to AWS KMS CMKs to requests from the VPC or VPC endpoint.

- `aws:SourceVpc` limits access to requests from the specified VPC.
- `aws:SourceVpce` limits access to requests from the specified VPC endpoint.

If you use these condition keys in a key policy statement that allows or denies access to AWS KMS CMKs, you might inadvertently deny access to services that use AWS KMS on your behalf.

Take care to avoid a situation like the [IP address condition keys \(p. 87\)](#) example. If you restrict requests for a CMK to a VPC or VPC endpoint, calls to AWS KMS from an integrated service, such as Amazon S3 or Amazon EBS, might fail. This can happen even if the source request ultimately originates in the VPC or from the VPC endpoint.

## AWS KMS Condition Keys

AWS KMS provides an additional set of predefined condition keys that you can use in key policies and IAM policies. These condition keys are specific to AWS KMS. For example, you can use the `kms:EncryptionContext` condition key to require a particular [encryption context \(p. 12\)](#) when controlling access to an AWS KMS symmetric customer master key (CMK).

### Conditions for an API operation request

Many of the AWS KMS condition keys control access to a CMK based on the value of a parameter in the request for an API operation. For example, you can use the `kms:CustomerMasterKeySpec` (p. 91) condition key in an IAM policy to allow use of the [CreateKey](#) operation only when the value of the `CustomerMasterKeySpec` parameter in the `CreateKey` request is `RSA_4096`.

This type of condition works even when the parameter doesn't appear in the request, such as when you use the parameter's default value. For example you can use the `kms:CustomerMasterKeySpec` (p. 91) condition key to allow users to use the `CreateKey` operation only when the value of the `CustomerMasterKeySpec` parameter is `SYMMETRIC_DEFAULT`, which is the default value. This condition allows requests that have the `CustomerMasterKeySpec` parameter with the `SYMMETRIC_DEFAULT` value and requests that have no `CustomerMasterKeySpec` parameter.

### Conditions for CMKs used in API operations

Some of the AWS KMS condition keys control access to operations based on a property of the CMK that is used in the operation. For example, you can use the `kms:KeyOrigin` (p. 106) condition to allow principals to call [GenerateDataKey](#) on a CMK only when the `Origin` of the CMK is `AWS_KMS`. To find out if a condition key can be used in this way, see the description of the condition key.

The operation must be a *CMK resource operation*, that is, an operation that is authorized for a particular CMK. To identify the CMK resource operations, in the [Actions and Resources Table \(p. 77\)](#), look for a value of `CMK` in the `Resources` column for the operation. If you use this type of condition key with an operation that is not authorized for a particular CMK resource, like [ListKeys](#), the permission is not effective because the condition can never be satisfied. There is no CMK resource involved in authorizing the `ListKeys` operation and no `CustomerMasterKeySpec` property.

The following topics describe each AWS KMS condition key and include example policy statements that demonstrate policy syntax.

### Topics

## kms:BypassPolicyLockoutSafetyCheck

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<a href="#">kms:BypassPolicyLockoutSafetyCheck</a>	<a href="#">Boolean</a>	CreateKey	IAM policies only
		PutKeyPolicy	Key policies and IAM policies

The `kms:BypassPolicyLockoutSafetyCheck` condition key controls access to the [CreateKey](#) and [PutKeyPolicy](#) operations based on the value of the `BypassPolicyLockoutSafetyCheck` parameter in the request.

The following example IAM policy statement prevents users from bypassing the policy lockout safety check by denying them permission to create CMKs when the value of the `BypassPolicyLockoutSafetyCheck` parameter in the `CreateKey` request is `true`.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": "kms:CreateKey",
    "Resource": "*",
    "Condition": {
      "Bool": {
        "kms:BypassPolicyLockoutSafetyCheck": true
      }
    }
  }
}
```

You can also use the `kms:BypassPolicyLockoutSafetyCheck` condition key in an IAM policy or key policy to control access to the `PutKeyPolicy` operation. The following example policy statement from

a key policy prevents users from bypassing the policy lockout safety check when changing the policy of a CMK.

Instead of using an explicit Deny, this policy statement uses Allow with the [Null condition operator](#) to allow access only when the request does not include the `BypassPolicyLockoutSafetyCheck` parameter. When the parameter is not used, the default value is `false`. This slightly weaker policy statement can be overridden in the rare case that a bypass is necessary.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Allow",
    "Action": "kms:PutKeyPolicy",
    "Resource": "*",
    "Condition": {
      "Null": {
        "kms:BypassPolicyLockoutSafetyCheck": true
      }
    }
  }
}
```

## kms:CallerAccount

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:CallerAccount	String	All AWS KMS operations <i>except</i> for <code>CreateKey</code> , <code>GenerateRandom</code> , <code>ListAliases</code> , <code>ListKeys</code> , <code>ListRetirableGrants</code> , and <code>RetireGrant</code> .	Key policies only

You can use this condition key to allow or deny access to all identities (IAM users and roles) in an AWS account. In key policies, you use the `Principal` element to specify the identities to which the policy statement applies. The syntax for the `Principal` element does not provide a way to specify all identities in an AWS account. But you can achieve this effect by combining this condition key with a `Principal` element that specifies all AWS identities.

For example, the following policy statement demonstrates how to use the `kms:CallerAccount` condition key. This policy statement is in the key policy for the AWS managed CMK for Amazon EBS. It combines a `Principal` element that specifies all AWS identities with the `kms:CallerAccount` condition key to effectively allow access to all identities in AWS account 11122223333. It contains an additional AWS KMS condition key (`kms:ViaService`) to further limit the permissions by only allowing requests that come through Amazon EBS. For more information, see [kms:ViaService](#) (p. 111).

```
{
```

```
{
  "Sid": "Allow access through EBS for all principals in the account that are authorized to
use EBS",
  "Effect": "Allow",
  "Principal": { "AWS": "*" },
  "Condition": {
    "StringEquals": {
      "kms:CallerAccount": "111122223333",
      "kms:ViaService": "ec2.us-west-2.amazonaws.com"
    }
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:CreateGrant",
    "kms:DescribeKey"
  ],
  "Resource": "*"
}
```

## kms:CustomerMasterKeySpec

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:CustomerMasterKeySpec	String	CreateKey  CMK resource operations	IAM policies  Key policies and IAM policies

The `kms:CustomerMasterKeySpec` condition key controls access to operations based on the value of the `CustomerMasterKeySpec` property of the CMK that is created by or used in the operation.

You can use this condition key in an IAM policy to control access to the [CreateKey](#) operation based on the value of the [CustomerMasterKeySpec](#) parameter in a `CreateKey` request. For example, you can use this condition to allow users to create only symmetric CMKs or only CMKs with RSA keys.

The following example IAM policy statement uses the `kms:CustomerMasterKeySpec` condition key to allow the principals to create a CMK only when the `CustomerMasterKeySpec` in the request is `RSA_4096`.

```
{
  "Effect": "Allow",
  "Action": "kms:CreateKey",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:CustomerMasterKeySpec": "RSA_4096"
    }
  }
}
```

You can also use the `kms:CustomerMasterKeySpec` condition key to control access to operations that use or manage a CMK based on the `CustomerMasterKeySpec` property of the CMK used for the operation. The operation must be a *CMK resource operation*, that is, an operation that is authorized for a particular CMK. To identify the CMK resource operations, in the [Actions and Resources Table \(p. 77\)](#), look for a value of `CMK` in the `Resources` column for the operation.

For example, the following IAM policy allows principals to perform the specified CMK resource operations, but only with the symmetric CMKs in the account.

```
{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:DescribeKey"
  ],
  "Resource": {
    "arn:aws:kms:us-west-2:111122223333:key/*"
  },
  "Condition": {
    "StringEquals": {
      "kms:CustomerMasterKeySpec": "SYMMETRIC_DEFAULT"
    }
  }
}
```

#### See Also

- [kms:CustomerMasterKeyUsage](#) (p. 92)
- [kms:DataKeyPairSpec](#) (p. 93)
- [kms:KeyOrigin](#) (p. 106)

## kms:CustomerMasterKeyUsage

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:CustomerMasterKeyUsage	String	CreateKey  CMK resource operations	IAM policies  Key policies and IAM policies

The `kms:CustomerMasterKeyUsage` condition key controls access to operations based on the value of the `KeyUsage` property of the CMK that is created by or used in the operation.

You can use this condition key to control access to the [CreateKey](#) operation based on the value of the [KeyUsage](#) parameter in the request. Valid values for `KeyUsage` are `ENCRYPT_DECRYPT` and `SIGN_VERIFY`.

For example, you can allow a user to create a CMK only when the `KeyUsage` is `ENCRYPT_DECRYPT` or deny a user permission when the `KeyUsage` is `SIGN_VERIFY`.

The following example IAM policy statement uses the `kms:CustomerMasterKeyUsage` condition key to allow a user to create a CMK only when the `KeyUsage` is `ENCRYPT_DECRYPT`.

```
{
  "Effect": "Allow",
  "Action": "kms:CreateKey",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
```

```

    "kms:CustomerMasterKeyUsage": "ENCRYPT_DECRYPT"
  }
}

```

You can also use the `kms:CustomerMasterKeyUsage` condition key to control access to operations that use or manage a CMK based on the `KeyUsage` property of the CMK used for the operation. The operation must be a *CMK resource operation*, that is, an operation that is authorized for a particular CMK. To identify the CMK resource operations, in the [Actions and Resources Table \(p. 77\)](#), look for a value of CMK in the `Resources` column for the operation.

For example, the following IAM policy allows principals to perform the specified CMK resource operations, but only with CMKs in the account that are used for signing and verification.

```

{
  "Effect": "Allow",
  "Action": [
    "kms:CreateGrant",
    "kms:DescribeKey",
    "kms:GetPublicKey",
    "kms:ScheduleKeyDeletion"
  ],
  "Resource": {
    "arn:aws:kms:us-west-2:111122223333:key/*"
  },
  "Condition": {
    "StringEquals": {
      "kms:CustomerMasterKeyUsage": "SIGN_VERIFY"
    }
  }
}

```

## kms:DataKeyPairSpec

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:DataKeySpec</code>	String	<code>GenerateDataKeyPair</code> <code>GenerateDataKeyPairWithoutPlaintext</code>	Key policies and IAM policies

You can use this condition key to control access to the [GenerateDataKeyPair](#) and [GenerateDataKeyPairWithoutPlaintext](#) operations based on the value of the `KeyPairSpec` parameter in the request. For example, you can allow a user to generate only particular types of data key pairs.

The following example key policy statement uses the `kms:DataKeyPairSpec` condition key to allow a user to use the CMK to generate only RSA data key pairs.

```

{
  "Effect": "Allow",

```

```
{
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": [
    "kms:GenerateDataKeyPair",
    "kms:GenerateDataKeyPairWithoutPlaintext"
  ],
  "Resource": "*",
  "Condition": {
    "StringLike": {
      "kms:DataKeyPairSpec": "RSA*"
    }
  }
}
```

#### See Also

- [kms:CustomerMasterKeySpec](#) (p. 91)
- the section called “[kms:EncryptionAlgorithm](#)” (p. 94)
- the section called “[kms:EncryptionContext](#)” (p. 96)
- the section called “[kms:EncryptionContextKeys](#)” (p. 100)

## kms:EncryptionAlgorithm

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:EncryptionAlgorithm</code>	String	Decrypt Encrypt GenerateDataKey GenerateDataKeyPair GenerateDataKeyPairWithoutPlaintext GenerateDataKeyWithoutPlaintext ReEncrypt	Key policies and IAM policies

You can use the `kms:EncryptionAlgorithm` condition key to control access to cryptographic operations based on the encryption algorithm that is used in the operation. For the [Encrypt](#), [Decrypt](#), and [ReEncrypt](#) operations, it controls access based on the value of the [EncryptionAlgorithm](#) parameter in the request. For operations that generate data keys and data key pairs, it controls access based on the encryption algorithm that is used to encrypt the data key.

This condition key has no effect on operations performed outside of AWS KMS, such as encrypting with the public key in an asymmetric CMK pair outside of AWS KMS.

#### EncryptionAlgorithm parameter in a request

To allow users to use only a particular encryption algorithm with a CMK, use a policy statement with a `Deny` effect and a `StringNotEquals` condition operator. For example, the following example key policy statement prohibits principals who can assume the `ExampleRole` role from using this symmetric CMK in the specified cryptographic operations unless the encryption algorithm in the request is `RSAES_OAEP_SHA_256`.

Unlike a policy statement that allows a user to use a particular encryption algorithm, a policy statement with a double-negative like this one prevents other policies and grants for this CMK from allowing this role to use other encryption algorithms. The Deny in this policy statement takes precedence over any key policy or IAM policy with an Allow effect, and it takes precedence over all grants for this CMK and its principals.

```
{
  "Sid": "Allow only one encryption algorithm with this asymmetric CMK",
  "Effect": "Deny",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/ExampleRole"
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*"
  ],
  "Resource": "*",
  "Condition": {
    "StringNotEquals": {
      "kms:EncryptionAlgorithm": "RSAES_OAEP_SHA_256"
    }
  }
}
```

### Encryption algorithm used for the operation

You can also use the `kms:EncryptionAlgorithm` condition key to control access to the operations that generate data keys and data key pairs. These operations use only symmetric CMKs and the `SYMMETRIC_DEFAULT` algorithm.

For example, this IAM policy limits its principals to symmetric encryption. It denies access to any CMK in the example account for cryptographic operations unless the encryption algorithm specified in the request or used in the operation is `SYMMETRIC_DEFAULT`. The addition of [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), [GenerateDataKeyPair](#), and [GenerateDataKeyPairWithoutPlaintext](#) have no immediate practical effect because you can't use an asymmetric CMK or asymmetric encryption algorithm to encrypt a data key or encrypt the private key in a data key pair.

```
{
  "Version": "2012-10-17",
  "Statement": {
    "Effect": "Deny",
    "Action": [
      "kms:Encrypt",
      "kms:Decrypt",
      "kms:ReEncrypt*",
      "kms:GenerateDataKey*",
      "kms:GenerateDataKeyPair*"
    ],
    "Resource": {
      "arn:aws:kms:us-west-2:111122223333:key/*"
    },
    "Condition": {
      "StringNotEquals": {
        "kms:EncryptionAlgorithm": "SYMMETRIC_DEFAULT"
      }
    }
  }
}
```

## kms:EncryptionContext:

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:EncryptionContext	String	CreateGrant Encrypt Decrypt GenerateDataKey GenerateDataKeyPair GenerateDataKeyPairWithoutPlaintext GenerateDataKeyWithoutPlaintext ReEncrypt	Key policies and IAM policies

You can use the `kms:EncryptionContext:` condition key prefix to control access to a [symmetric CMK \(p. 130\)](#) based on the encryption context in a request for a cryptographic operation. Use this condition key prefix to evaluate both the key and the value in the encryption context pair. To evaluate only the encryption context keys, use the [kms:EncryptionContextKeys \(p. 100\)](#) condition key.

An [encryption context \(p. 12\)](#) is a set of nonsecret key–value pairs that you can include in a request for any AWS KMS cryptographic operation ([Encrypt](#), [Decrypt](#), [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), and [ReEncrypt](#)) that uses a symmetric CMK, and the [CreateGrant](#) operation. When you specify an encryption context in an encryption operation, you must specify the same encryption context in the decryption operation. Otherwise, the decryption request fails.

You cannot specify an encryption context in a cryptographic operation with an [asymmetric CMK \(p. 130\)](#). The standard asymmetric encryption algorithms that AWS KMS uses do not support an encryption context.

To use the `kms:EncryptionContext:` condition key prefix, replace the `encryption_context_key` placeholder with the encryption context key. Replace the `encryption_context_value` placeholder with the encryption context value.

```
"kms:EncryptionContext:encryption_context_key": "encryption_context_value"
```

For example, the following condition key specifies an encryption context in which the key is `AppName` and the value is `ExampleApp`.

```
"kms:EncryptionContext:AppName": "ExampleApp"
```

The following example key policy statement uses this condition key. Because there can be multiple encryption context pairs in a request, the [condition operator](#) must include `ForAnyValue` or `ForAllValues`.

This policy allows the principal to use the CMK in a `GenerateDataKey` request only when at least one of the encryption context pairs in the request is `"AppName": "ExampleApp"`.

```
{
```

```
"Effect": "Allow",
"Principal": {
  "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
},
"Action": "kms:GenerateDataKey",
"Resource": "*",
"Condition": {
  "ForAnyValue:StringEquals": {
    "kms:EncryptionContext:AppName": "ExampleApp"
  }
}
```

## Requiring multiple encryption context pairs

To require more than one encryption context pair, you can include multiple instances of the `kms:EncryptionContext` condition. For example, the following example policy statement uses the `ForAllValues` operator to require both of the following encryption context pairs (and no others). The order in which the pairs are specified does not matter.

- `"AppName": "ExampleApp"`
- `"FilePath": "/var/opt/secrets/"`

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": "kms:GenerateDataKey",
  "Resource": "*",
  "Condition": {
    "ForAllValues:StringEquals": {
      "kms:EncryptionContext:AppName": "ExampleApp",
      "kms:EncryptionContext:FilePath": "/var/opt/secrets/"
    }
  }
}
```

## Case sensitivity of the encryption context condition

The encryption context that is specified in a decryption operation must be an exact, case-sensitive match for the encryption context that is specified in the encryption operation. Only the order of pairs in an encryption context with multiple pair can vary.

However, in policy conditions, the condition key is not case sensitive. The case sensitivity of the condition value is determined by the [policy condition operator](#) that you use, such as `StringEquals` or `StringEqualsIgnoreCase`.

As such, the condition key, which consists of the `kms:EncryptionContext:` prefix and the `encryption_context_key` replacement, is not case sensitive. A policy that uses this condition does not check the case of either element of the condition key. The case sensitivity of the value, that is, the `encryption_context_value` replacement, is determined by the policy condition operator.

For example, the following policy statement allows the operation when the encryption context includes an `AppName` key, regardless of its capitalization. The `StringEquals` condition requires that `ExampleApp` be capitalized as it is specified.

```
{
  "Effect": "Allow",
```

```
"Principal": {
  "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
},
"Action": "kms:Decrypt",
"Resource": "*",
"Condition": {
  "ForAnyValue:StringEquals": {
    "kms:EncryptionContext:Appname": "ExampleApp"
  }
}
}
```

To require a case-sensitive encryption context key, use the [kms:EncryptionContextKeys \(p. 100\)](#) policy condition with a case-sensitive condition operator, such as `StringEquals`. In this policy condition, because the encryption context key is the policy condition value, its case sensitivity is determined by the condition operator.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": "kms:GenerateDataKey",
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContextKey": "AppName"
    }
  }
}
```

To require a case-sensitive evaluation of both the encryption context key and value, use the `kms:EncryptionContextKeys` and `kms:EncryptionContext` policy conditions together in the same policy statement. For example, in the following example policy statement, because the `StringEquals` operator is case sensitive, both the encryption context key and the encryption context value are case sensitive.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": "kms:GenerateDataKey",
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContextKeys": "AppName",
      "kms:EncryptionContext:AppName": "ExampleApp"
    }
  }
}
```

## Using variables in an encryption context condition

The key and value in an encryption context pair must be simple literal strings. They cannot be integers or objects, or any type that is not fully resolved. If you use a different type, such as an integer or float, AWS KMS interprets it as a literal string.

```
"encryptionContext": {
  "department": "10103.0"
```

```
}
```

However, the value in the `kms:EncryptionContext:` condition key pair can be an [IAM policy variable](#). These policy variables are resolved at runtime based on values in the request. For example, `aws:CurrentTime` resolves to the time of the request and `aws:username` resolves to the friendly name of the caller.

You can use these policy variables to create a policy statement with a condition that requires very specific information in an encryption context, such as the caller's user name. Because it contains a variable, you can use the same policy statement for all users who can assume the role. You don't have to write a separate policy statement for each user.

Consider a situation where you want to all users who can assume a role to use the same CMK to encrypt and decrypt their data. However, you want to allow them to decrypt only the data that they encrypted. Start by requiring that every request to AWS KMS include an encryption context where the key is `user` and the value is the caller's AWS user name, such as the following one.

```
"encryptionContext": {
  "user": "bob"
}
```

Then, to enforce this requirement, you can use a policy statement like the one in the following example. This policy statement gives the `TestTeam` role permission to encrypt and decrypt data with the CMK. However, the permission is valid only when the encryption context in the request includes a `"user": "<username>"` pair. To represent the user name, the condition uses the `aws:username` policy variable.

When the request is evaluated, the caller's user name replaces the variable in the condition. As such, the condition requires an encryption context of `"user": "bob"` for "bob" and `"user": "alice"` for "alice."

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/TestTeam"
  },
  "Action": [
    "kms:Decrypt",
    "kms:Encrypt"
  ],
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContext:user": "${aws:username}"
    }
  }
}
```

You can use an IAM policy variable only in the value of the `kms:EncryptionContext:` condition key pair. You cannot use a variable in the key.

You can also use [provider-specific context keys](#) in variables. These context keys uniquely identify users who logged into AWS by using web identity federation.

Like all variables, these variables can be used only in the `kms:EncryptionContext:` policy condition, not in the actual encryption context. And they can be used only in the value of the condition, not in the key.

For example, the following key policy statement is similar to the previous one. However, the condition requires an encryption context where the key is `sub` and the value uniquely identifies a user logged into

a Amazon Cognito user pool. For details about identifying users and roles in Amazon Cognito, see [IAM Roles](#) in the [Amazon Cognito Developer Guide](#).

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/TestTeam"
  },
  "Action": [
    "kms:Decrypt",
    "kms:Encrypt"
  ]
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContext:sub": "#{cognito-identity.amazonaws.com:sub}"
    }
  }
}
```

## kms:EncryptionContextKeys

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:EncryptionContextKeys	Strings(list)	CreateGrant Decrypt Encrypt GenerateDataKey GenerateDataKeyPair GenerateDataKeyPairWithoutPlaintext GenerateDataKeyWithoutPlaintext ReEncrypt	Key policies and IAM policies

You can use the `kms:EncryptionContextKeys` condition key to control access to a CMK based on the encryption context in a request for a cryptographic operation that uses a [symmetric CMK \(p. 130\)](#). Use this condition key prefix to evaluate only the key in each encryption context pair. To evaluate both the key and the value, use the [kms:EncryptionContext: \(p. 96\)](#) condition key prefix.

You cannot specify an encryption context in a cryptographic operation with an [asymmetric CMK \(p. 130\)](#). The standard asymmetric encryption algorithms that AWS KMS uses do not support an encryption context.

You can use this condition key to control access based on the [encryption context \(p. 12\)](#) in the AWS KMS API request. Encryption context is a set of key–value pairs that you can include in AWS KMS cryptographic operations ([Encrypt](#), [Decrypt](#), [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), and

[ReEncrypt](#)) and the [CreateGrant](#) operation. Because there can be multiple encryption context pairs in a request, the [condition operator](#) must include `ForAnyValue` or `ForAllValues`.

The following example policy statement uses the `kms:EncryptionContextKeys` condition key to allow use of a CMK for the specified operations only when at least one of the encryption context pairs in the request includes the `AppName` key, regardless of its value.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": [
    "kms:Encrypt",
    "kms:GenerateDataKey*"
  ],
  "Resource": "*",
  "Condition": {
    "ForAnyValue:StringEquals": {
      "kms:EncryptionContextKeys": "AppName"
    }
  }
}
```

Because the [StringEquals](#) condition operation is case sensitive, the previous policy statement requires the spelling and case of the encryption context key. But you can use a condition operator that ignores the case of the key, such as `StringEqualsIgnoreCase`.

You can specify multiple encryption context keys in each condition. For example, the following policy statement uses the `ForAllValues` and `StringEquals` condition operators to allow the specified operations only when the encryption context in the request includes both the `AppName` and `FilePath` keys (and no others), regardless of their values. The order of keys in the encryption context does not matter.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": [
    "kms:Encrypt",
    "kms:GenerateDataKey*"
  ],
  "Resource": "*",
  "Condition": {
    "ForAllValues:StringEquals": {
      "kms:EncryptionContextKeys": [
        "AppName",
        "FilePath"
      ]
    }
  }
}
```

You can also use the `kms:EncryptionContextKeys` condition key to require an encryption context in cryptographic operations that use the CMK.

The following example key policy statement uses the `kms:EncryptionContextKeys` condition key with the [Null condition operator](#) to allow access to CMK only when the `kms:EncryptionContextKeys` condition key exists (is not null) in the API request. It does not check the keys or values of the encryption context, only that the encryption context exists.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/RoleForExampleApp"
  },
  "Action": [
    "kms:Encrypt",
    "kms:GenerateDataKey*"
  ],
  "Resource": "*",
  "Condition": {
    "Null": {
      "kms:EncryptionContextKeys": false
    }
  }
}
```

## kms:ExpirationModel

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:ExpirationModel</code>	String	<code>ImportKeyMaterial</code>	Key policies and IAM policies

The `kms:ExpirationModel` condition key controls access to the [ImportKeyMaterial](#) operation based on the value of the [ExpirationModel](#) parameter in the request.

`ExpirationModel` is an optional parameter that determines whether the imported key material expires. Valid values are `KEY_MATERIAL_EXPIRES` and `KEY_MATERIAL_DOES_NOT_EXPIRE`. `KEY_MATERIAL_EXPIRES` is the default value.

The expiration date and time is determined by the value of the [ValidTo](#) parameter. The `ValidTo` parameter is required unless the value of the `ExpirationModel` parameter is `KEY_MATERIAL_DOES_NOT_EXPIRE`. You can also use the [kms:ValidTo](#) (p. 110) condition key to require a particular expiration date as a condition for access.

The following example policy statement uses the `kms:ExpirationModel` condition key to allow a user to import key material into a CMK only when the request includes the `ExpirationModel` parameter and its value is `KEY_MATERIAL_DOES_NOT_EXPIRE`.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:ImportKeyMaterial",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:ExpirationModel": "KEY_MATERIAL_DOES_NOT_EXPIRE"
    }
  }
}
```

```
}  
}
```

You can also use the `kms:ExpirationModel` condition key to allow a user to import key material only when the key material expires, without [specifying an expiration date \(p. 110\)](#) in the condition. The following example policy statement uses the `kms:ExpirationModel` condition key with the [Null condition operator](#) to allow a user to import key material only when the request does not have an `ExpirationModel` parameter.

```
{  
  "Effect": "Allow",  
  "Principal": {  
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"  
  },  
  "Action": "kms:ImportKeyMaterial",  
  "Resource": "*",  
  "Condition": {  
    "Null": {  
      "kms:ExpirationModel": true  
    }  
  }  
}
```

## kms:GrantConstraintType

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:GrantConstraintType</code>	String	<code>CreateGrant</code>	Key policies and IAM policies

You can use this condition key to control access to the [CreateGrant](#) operation based on the type of [grant constraint](#) in the request.

When you create a grant, you can optionally specify a grant constraint to allow the operations that the grant permit only when a particular [encryption context \(p. 12\)](#) is present. The grant constraint can be one of two types: `EncryptionContextEquals` or `EncryptionContextSubset`. You can use this condition key to check that the request contains one type or the other.

The following example policy statement uses the `kms:GrantConstraintType` condition key to allow a user to create grants only when the request includes an `EncryptionContextEquals` grant constraint. The example shows a policy statement in a key policy.

```
{  
  "Effect": "Allow",  
  "Principal": {  
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"  
  },  
  "Action": "kms:CreateGrant",
```

```
"Resource": "*",
"Condition": {
  "StringEquals": {
    "kms:GrantConstraintType": "EncryptionContextEquals"
  }
}
```

## kms:GrantIsForAWSResource

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:GrantIsForAWSResource	Boolean	CreateGrant ListGrants RevokeGrant	Key policies and IAM policies

Allows or denies access to the [CreateGrant](#), [ListGrants](#), or [RevokeGrant](#) operations when any of the [AWS services that is integrated with AWS KMS](#) performs the grant operation on the user's behalf. This condition key does not affect the user's permissions to perform the grant operation directly.

For example, the following key policy statement uses the `kms:GrantIsForAWSResource` condition key. It allows a user to create grants on this CMK only when the grant is created on the user's behalf by any one of the integrated services. It does not allow the user to create grants directly.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:CreateGrant",
  "Resource": "*",
  "Condition": {
    "Bool": {
      "kms:GrantIsForAWSResource": true
    }
  }
}
```

#### See Also

- [kms:RetiringPrincipal](#) (p. 108)

## kms:GrantOperations

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:GrantOperations	String	CreateGrant	Key policies and IAM policies

You can use this condition key to control access to the [CreateGrant](#) operation based on the grant operations in the request. For example, you can allow a user to create grants that delegate permission to encrypt but not decrypt.

The following example policy statement uses the `kms:GrantOperations` condition key to allow a user to create grants that delegate permission to encrypt and re-encrypt when this CMK is the destination CMK. The example shows a policy statement in a key policy.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:CreateGrant",
  "Resource": "*",
  "Condition": {
    "ForAllValues:StringEquals": {
      "kms:GrantOperations": [
        "Encrypt",
        "ReEncryptTo"
      ]
    }
  }
}
```

### See Also

## kms:GranteePrincipal

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:GranteePrincipal	String	CreateGrant	IAM and key policies

You can use this condition key to control access to the [CreateGrant](#) operation based on the value of the [GranteePrincipal](#) parameter in the request. For example, you can allow a user to create grants to use a

CMK only when the grantee principal in the `CreateGrant` request matches the principal specified in the condition statement.

The following example policy statement uses the `kms:GranteePrincipal` condition key to allow a user to create grants for a CMK only when the grantee principal in the grant is the `LimitedAdminRole`.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:CreateGrant",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:GranteePrincipal": "arn:aws:iam::111122223333:role/LimitedAdminRole"
    }
  }
}
```

#### See Also

- [kms:GrantConstraintType](#) (p. 103)

## kms:KeyOrigin

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:KeyOrigin	String	CreateKey  CMK resource operations	IAM policies  Key policies and IAM policies

The `kms:KeyOrigin` condition key controls access to operations based on the value of the `Origin` property of the CMK that is created by or used in the operation.

You can use this condition key to control access to the [CreateKey](#) operation based on the value of the [Origin](#) parameter in the request. Valid values for `Origin` are `AWS_KMS`, `AWS_CLOUDHSM`, and `EXTERNAL`.

For example, you can allow a user to create a CMK only when the key material is generated in KMS (`AWS_KMS`), only when the key material is generated in an AWS CloudHSM cluster that is associated with a [custom key store](#) (p. 172) (`AWS_CLOUDHSM`), or only when the [key material is imported](#) (p. 147) from an external source (`EXTERNAL`).

The following example policy statement uses the `kms:KeyOrigin` condition key to allow a user to create a CMK only when AWS KMS creates the key material.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
}
```

```

    "Action": "kms:CreateKey",
    "Resource": "*",
    "Condition": {
      "StringEquals": {
        "kms:KeyOrigin": "AWS_KMS"
      }
    }
  }
}

```

You can also use the `kms:KeyOrigin` condition key to control access to operations that use or manage a CMK based on the `Origin` property of the CMK used for the operation. The operation must be a *CMK resource operation*, that is, an operation that is authorized for a particular CMK. To identify the CMK resource operations, in the [Actions and Resources Table \(p. 77\)](#), look for a value of `CMK` in the `Resources` column for the operation.

For example, the following IAM policy allows principals to perform the specified CMK resource operations, but only with CMKs in the account that were created in a custom key store.

```

{
  "Effect": "Allow",
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:GenerateDataKey",
    "kms:GenerateDataKeyWithoutPlaintext",
    "kms:GenerateDataKeyPair",
    "kms:GenerateDataKeyPairWithoutPlaintext",
    "kms:ReEncrypt*"
  ],
  "Resource": {
    "arn:aws:kms:us-west-2:111122223333:key/*"
  },
  "Condition": {
    "StringEquals": {
      "kms:KeyOrigin": "AWS_CLOUDHSM"
    }
  }
}

```

- [kms:CustomerMasterKeyUsage \(p. 92\)](#)

## kms:MessageType

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:MessageType</code>	String	Sign Verify	Key policies and IAM policies

The `kms:MessageType` condition key controls access to the [Sign](#) and [Verify](#) operations based on the value of the `MessageType` parameter in the request. Valid values for `MessageType` are `RAW` and `DIGEST`.

For example, the following key policy statement uses the `kms:MessageType` condition key to allow a user to use an asymmetric CMK to sign a message, but not a message digest.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:Sign",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:MessageType": "RAW"
    }
  }
}
```

#### See Also

- [the section called “kms:SigningAlgorithm” \(p. 109\)](#)

## kms:ReEncryptOnSameKey

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:ReEncryptOnSameKey</code>	Boolean	ReEncrypt	Key policies and IAM policies

You can use this condition key to control access to the [ReEncrypt](#) operation based on whether the request specifies a destination CMK that is the same one used for the original encryption. For example, the following policy statement uses the `kms:ReEncryptOnSameKey` condition key to allow a user to reencrypt only when the destination CMK is the same one used for the original encryption. The example shows a policy statement in a key policy.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:ReEncrypt*",
  "Resource": "*",
  "Condition": {
    "Bool": {
      "kms:ReEncryptOnSameKey": true
    }
  }
}
```

## kms:RetiringPrincipal

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:RetiringPrincipal</code>	String (list)	CreateGrant	Key policies and IAM policies

You can use this condition key to control access to the [CreateGrant](#) operation based on the value of the [RetiringPrincipal](#) parameter in the request. For example, you can allow a user to create grants to use a CMK only when the `RetiringPrincipal` in the `CreateGrant` request matches the `RetiringPrincipal` in the condition statement.

The following example policy statement allows a user to create grants for the CMK. The `kms:RetiringPrincipal` condition key restricts the permission to `CreateGrant` requests where the retiring principal in the grant is either the `LimitedAdminRole` or the `OpsAdmin` user.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:CreateGrant",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:RetiringPrincipal": [
        "arn:aws:iam::111122223333:role/LimitedAdminRole",
        "arn:aws:iam::111122223333:user/OpsAdmin"
      ]
    }
  }
}
```

## kms:SigningAlgorithm

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
<code>kms:SigningAlgorithm</code>	String	Sign Verify	Key policies and IAM policies

You can use the `kms:SigningAlgorithm` condition key to control access to the [Sign](#) and [Verify](#) operations based on the value of the [SigningAlgorithm](#) parameter in the request. This condition key has no effect on operations performed outside of AWS KMS, such as verifying signatures with the public key in an asymmetric CMK pair outside of AWS KMS.

The following example key policy allows users who can assume the `testers` role to use the CMK to sign messages only when the signing algorithm used for the request is an `RSASSA_PSS` algorithm, such as `RSASSA_PSS_SHA512`.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:role/testers"
  }
}
```

```
{
  },
  "Action": "kms:Sign",
  "Resource": "*",
  "Condition": {
    "StringLike": {
      "kms:SigningAlgorithm": "RSASSA_PSS*"
    }
  }
}
```

#### See Also

- [kms:EncryptionAlgorithm](#) (p. 94)
- [the section called “kms:MessageType”](#) (p. 107)

## kms:ValidTo

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:ValidTo	Timestamp	ImportKeyMaterial	Key policies and IAM policies

The `kms:ValidTo` condition key controls access to the [ImportKeyMaterial](#) operation based on the value of the [ValidTo](#) parameter in the request, which determines when the imported key material expires. The value is expressed in [Unix time](#).

By default, the `ValidTo` parameter is required in an `ImportKeyMaterial` request. However, if the value of the [ExpirationModel](#) parameter is `KEY_MATERIAL_DOES_NOT_EXPIRE`, the `ValidTo` parameter is invalid. You can also use the [kms:ExpirationModel](#) (p. 102) condition key to require the `ExpirationModel` parameter or a specific parameter value.

The following example policy statement allows a user to import key material into a CMK. The `kms:ValidTo` condition key limits the permission to `ImportKeyMaterial` requests where the `ValidTo` value is less than or equal to 1546257599.0 (December 31, 2018 11:59:59 PM).

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:ImportKeyMaterial",
  "Resource": "*",
  "Condition": {
    "NumericLessThanEquals": {
      "kms:ValidTo": "1546257599.0"
    }
  }
}
```

#### See Also

- [kms:ExpirationModel](#) (p. 102)
- [kms:WrappingAlgorithm](#) (p. 113)
- [kms:WrappingKeySpec](#) (p. 114)

## kms:ViaService

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:ViaService	String	The kms:ViaService condition key is valid for all AWS KMS operations except: <a href="#">CreateKey</a> , <a href="#">GenerateRandom</a> , <a href="#">ListAliases</a> , <a href="#">ListKeys</a> , <a href="#">ListRetirableGrants</a> , <a href="#">RetireGrant</a> , and the API operations that create and manage <a href="#">custom key stores</a> (p. 172).	Key policies and IAM policies

The kms:ViaService condition key limits use of an AWS KMS [customer master key](#) (p. 2) (CMK) to requests from specified AWS services. You can specify one or more services in each kms:ViaService condition key.

For example, the following statement from a key policy uses the kms:ViaService condition key to allow a [customer managed CMK](#) (p. 3) to be used for the specified actions only when the request comes from Amazon EC2 or Amazon RDS in the US West (Oregon) region on behalf of ExampleUser.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": [
    "kms:Encrypt",
    "kms:Decrypt",
    "kms:ReEncrypt*",
    "kms:GenerateDataKey*",
    "kms:CreateGrant",
    "kms:ListGrants",
    "kms:DescribeKey"
  ],
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:ViaService": [
        "ec2.us-west-2.amazonaws.com",
        "rds.us-west-2.amazonaws.com"
      ]
    }
  }
}
```

You can also use a kms:ViaService condition key to deny permission to use a CMK when the request comes from particular services. For example, the following policy statement from a key policy uses a kms:ViaService condition key to prevent a customer managed CMK from being used for Encrypt operations when the request comes from AWS Lambda on behalf of ExampleUser.

```
{
```

```

"Effect": "Deny",
"Principal": {
  "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
},
"Action": [
  "kms:Encrypt"
],
"Resource": "*",
"Condition": {
  "StringEquals": {
    "kms:ViaService": [
      "lambda.us-west-2.amazonaws.com"
    ]
  }
}
}

```

### Important

When you use the `kms:ViaService` condition key, the service makes the request on behalf of a principal in the AWS account. These principals must have the following permissions:

- Permission to use the CMK. The principal needs to grant these permissions to the integrated service so the service can use the customer managed CMK on behalf of the principal. For more information, see [How AWS Services use AWS KMS \(p. 228\)](#).
- Permission to use the integrated service. For details about giving users access to an AWS service that integrates with AWS KMS, consult the documentation for the integrated service.

All [AWS managed CMKs \(p. 4\)](#) use a `kms:ViaService` condition key in their key policy document. This condition allows the CMK to be used only for requests that come from the service that created the CMK. To see the key policy for an AWS managed CMK, use the [GetKeyPolicy](#) operation.

The `kms:ViaService` condition key is valid in IAM and key policy statements. The services that you specify must be [integrated with AWS KMS](#) and support the `kms:ViaService` condition key.

The following table lists AWS services that are integrated with AWS KMS, support customer managed CMKs, and support the use of the `kms:ViaService` condition key in customer managed CMKs. The services in this table might not be available in all regions.

### Services that support the `kms:ViaService` condition key in customer managed CMKs

Service Name	KMS ViaService Name
AWS Backup	backup. <i>AWS_region</i> .amazonaws.com
Amazon Connect	connect. <i>AWS_region</i> .amazonaws.com
AWS Database Migration Service (AWS DMS)	dms. <i>AWS_region</i> .amazonaws.com
AWS Directory Service	directoryservice. <i>AWS_region</i> .amazonaws.com
Amazon EC2 Systems Manager	ssm. <i>AWS_region</i> .amazonaws.com
Amazon Elastic Block Store (Amazon EBS)	ec2. <i>AWS_region</i> .amazonaws.com (EBS only)
Amazon Elastic File System	elasticfilesystem. <i>AWS_region</i> .amazonaws.com
Amazon Elasticsearch Service	es. <i>AWS_region</i> .amazonaws.com
Amazon FSx	fsx. <i>AWS_region</i> .amazonaws.com
AWS Glue	glue. <i>AWS_region</i> .amazonaws.com

Service Name	KMS ViaService Name
Amazon Kinesis	kinesis. <i>AWS_region</i> .amazonaws.com
Amazon Kinesis Video Streams	kinesisvideo. <i>AWS_region</i> .amazonaws.com
AWS Lambda	lambda. <i>AWS_region</i> .amazonaws.com
Amazon Lex	lex. <i>AWS_region</i> .amazonaws.com
Amazon Managed Streaming for Apache Kafka	kafka. <i>AWS_region</i> .amazonaws.com
Amazon Neptune	rds. <i>AWS_region</i> .amazonaws.com
Amazon Redshift	redshift. <i>AWS_region</i> .amazonaws.com
Amazon Relational Database Service (Amazon RDS)	rds. <i>AWS_region</i> .amazonaws.com
Amazon RDS Performance Insights	rds. <i>AWS_region</i> .amazonaws.com
AWS Secrets Manager (Secrets Manager)	secretsmanager. <i>AWS_region</i> .amazonaws.com
Amazon Simple Email Service (Amazon SES)	ses. <i>AWS_region</i> .amazonaws.com
Amazon Simple Notification Service (Amazon SNS)	sns. <i>AWS_region</i> .amazonaws.com
Amazon Simple Storage Service (Amazon S3)	s3. <i>AWS_region</i> .amazonaws.com
AWS Snowball	importexport. <i>AWS_region</i> .amazonaws.com
Amazon SQS	sqs. <i>AWS_region</i> .amazonaws.com
Amazon WorkMail	workmail. <i>AWS_region</i> .amazonaws.com
Amazon WorkSpaces	workspaces. <i>AWS_region</i> .amazonaws.com
AWS X-Ray	xray. <i>AWS_region</i> .amazonaws.com

## kms:WrappingAlgorithm

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:WrappingAlgorithm	String	GetParametersForImport	Key policies and IAM policies

This condition key controls access to the [GetParametersForImport](#) operation based on the value of the [WrappingAlgorithm](#) parameter in the request. You can use this condition to require principals to use a particular algorithm to encrypt key material during the import process. Requests for the required public key and import token fail when they specify a different wrapping algorithm.

The following example policy statement uses the `kms:WrappingAlgorithm` condition key to give the example user permission to call the `GetParametersForImport` operation, but prevents them from using the `RSAES_OAEP_SHA_1` wrapping algorithm. When the `WrappingAlgorithm` in the `GetParametersForImport` request is `RSAES_OAEP_SHA_1`, the operation fails.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:GetParametersForImport",
  "Resource": "*",
  "Condition": {
    "StringNotEquals": {
      "kms:WrappingAlgorithm": "RSAES_OAEP_SHA_1"
    }
  }
}
```

#### See Also

- [kms:ExpirationModel](#) (p. 102)
- [kms:ValidTo](#) (p. 110)
- [kms:WrappingKeySpec](#) (p. 114)

## kms:WrappingKeySpec

AWS KMS Condition Keys	Condition Type	API Operations	Policy Type
kms:WrappingKeySpec	String	GetParametersForImport	Key policies and IAM policies

This condition key controls access to the [GetParametersForImport](#) operation based on the value of the [WrappingKeySpec](#) parameter in the request. You can use this condition to require principals to use a particular type of public key during the import process. If the request specifies a different key type, it fails.

Because the only valid value for the `WrappingKeySpec` parameter value is `RSA_2048`, preventing users from using this value effectively prevents them from using the `GetParametersForImport` operation.

The following example policy statement uses the `kms:WrappingAlgorithm` condition key to require that the `WrappingKeySpec` in the request is `RSA_2048`.

```
{
  "Effect": "Allow",
  "Principal": {
    "AWS": "arn:aws:iam::111122223333:user/ExampleUser"
  },
  "Action": "kms:GetParametersForImport",
  "Resource": "*",
  "Condition": {
    "StringEquals": {
      "kms:WrappingKeySpec": "RSA_2048"
    }
  }
}
```

#### See Also

- [kms:ValidTo](#) (p. 110)
- [kms:WrappingAlgorithm](#) (p. 113)

## Using Grants

AWS KMS supports two resource-based access control mechanisms: [key policies](#) (p. 50) and *grants*. With grants you can programmatically delegate the use of KMS customer master keys (CMKs) to other AWS principals. You can use them to allow access, but not deny it. Because grants can be very specific, and are easy to create and revoke, they are often used to provide temporary permissions or more granular permissions.

You can also use key policies to allow other principals to access a CMK, but key policies work best for relatively static permission assignments. Also, key policies use the standard permissions model for AWS policies in which users either have or do not have permission to perform an action with a resource. For example, users with the `kms:PutKeyPolicy` permission for a CMK can completely replace the key policy for a CMK with a different key policy of their choice. To enable more granular permissions management, use grants.

For code examples that demonstrate how to work with grants, see [Working with Grants](#) (p. 337).

## Create a Grant

To create a grant, call the [CreateGrant](#) operation. Specify a CMK, the grantee principal that the grant allows to use the CMK, and a list of allowed operations. The `CreateGrant` operation returns a grant ID that you can use to identify the grant in subsequent operations. To customize the grant, use optional `Constraints` parameters to define [grant constraints](#).

For example, the following `CreateGrant` command creates a grant that allows `exampleUser` to call the [Decrypt](#) operation on the specified [symmetric CMK](#) (p. 130). The grant uses the `RetiringPrincipal` parameter to designate a principal that can retire the grant. It also includes a grant constraint that allows the permission only when the [encryption context](#) (p. 12) in the request includes `"Department": "IT"`.

```
$ aws kms create-grant \
  --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
  --grantee-principal arn:aws:iam::111122223333:user/exampleUser \
  --operations Decrypt \
  --retiring-principal arn:aws:iam::111122223333:role/adminRole \
  --constraints EncryptionContextSubset={Department=IT}
```

To view the grant, use the [ListGrants](#) operation.

```
$ aws kms list-grants --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
{
  "Grants": [
    {
      "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "CreationDate": 1572216195.0,
      "GrantId": "abcde1237f76e4ba7987489ac329fbfba6ad343d6f7075dbd1ef191f0120514",
      "Constraints": {
        "EncryptionContextSubset": {
          "Department": "IT"
        }
      },
      "RetiringPrincipal": "arn:aws:iam::111122223333:role/adminRole",
```

```
    "Name": "",
    "IssuingAccount": "arn:aws:iam::111122223333:root",
    "GranteePrincipal": "arn:aws:iam::111122223333:user/exampleUser",
    "Operations": [
      "Decrypt"
    ]
  }
}
```

Grants can be revoked (deleted) by any user who has the [kms:RevokeGrant](#) permission on the CMK.

Grants can be retired by any of the following principals:

- The AWS account (root user) in which the grant was created
- The retiring principal in the grant, if any
- The grantee principal, if the grant includes [kms:RetireGrant](#) permission

## Grants for Symmetric and Asymmetric CMKs

You can create a grant that controls access to a symmetric CMK or an asymmetric CMK. However, you cannot create a grant that allows a principal to perform an operation that is not supported by the CMK. If you try, AWS KMS returns a `ValidationError` exception.

### Symmetric CMKs

Grants for symmetric CMKs cannot allow the [Sign](#), [Verify](#), or [GetPublicKey](#) operations. (There are limited exceptions to this rule for legacy operations, but you should not create a grant for an operation that AWS KMS does not support.)

### Asymmetric CMKs

Grants for asymmetric CMKs cannot allow operations that generate data keys or data key pairs. They also cannot allow operations related to [automatic key rotation](#) (p. 142), [imported key material](#) (p. 147), or CMKs in [custom key stores](#) (p. 172).

Grants for CMKs with a key usage of `SIGN_VERIFY` cannot allow encryption operations. Grants for CMKs with a key usage of `ENCRYPT_DECRYPT` cannot allow the `Sign` or `Verify` operations.

## Grant Constraints

[Grant constraints](#) set conditions on the permissions that the grantee principal can perform. AWS KMS supports two supported constraints, both of which involve the [encryption context](#) (p. 12) in a request for a cryptographic operation.

### Note

You cannot use encryption context grant constraints in a grant for an asymmetric CMK. The asymmetric encryption algorithms that AWS KMS uses do not support an encryption context.

- `EncryptionContextEquals` specifies that the grant applies only when the encryption context pairs in the request are an exact, case-sensitive match for the encryption context pairs in the grant constraint. The pairs can appear in any order, but the keys and values in each pair cannot vary.
- `EncryptionContextSubset` specifies that the grant applies only when the encryption context in the request includes the encryption context specified in the grant constraint. The encryption context in the request must be an exact, case-sensitive match of the encryption context in the constraint, but it can include additional encryption context pairs. The pairs can appear in any order, but the keys and values in each included pair cannot vary.

For example, consider a grant that allows [GenerateDataKey](#) and [Decrypt](#) operations. It includes an `EncryptionContextSubset` constraint with the following values.

```
{ "Department": "Finance", "Classification": "Public" }
```

In this example, any of the following encryption context values would satisfy the `EncryptionContextSubset` constraint.

- { "Department": "Finance", "Classification": "Public" }
- { "Classification": "Public", "Department": "Finance" }
- { "Customer": "12345", "Department": "Finance", "Classification": "Public", "Purpose": "Test" }

However, the following encryption context values would not satisfy the constraint, either because they are incomplete or do not include an exact, case-sensitive match of the specified pairs.

- { "Department": "Finance" }
- { "department": "finance", "classification": "public" }
- { "Classification": "Public", "Customer": "12345" }

## Authorizing CreateGrant in a Key Policy

When you create a key policy to control access to the [CreateGrant](#) operation, you can use one or more policy conditions to limit the permission. AWS KMS supports all of the following grant-related condition keys. For detailed information about these condition keys, see [AWS KMS Condition Keys \(p. 88\)](#).

- [kms:GrantConstraintType \(p. 103\)](#)
- [kms:GrantIsForAWSResource \(p. 104\)](#)
- [kms:GrantOperations \(p. 105\)](#)
- [kms:GranteePrincipal \(p. 105\)](#)
- [kms:RetiringPrincipal \(p. 108\)](#)

## Granting CreateGrant Permission

When a grant includes permission to call the `CreateGrant` operation, the grant only allows the grantee principal to create grants that are equally restrictive or more restrictive.

For example, consider a grant that allows the grantee principal to call the `GenerateDataKey`, `Decrypt`, and `CreateGrant` operations. The grantee principal can use this permission to create a grant that includes any subset of the operations specified in the parent grant, such as `GenerateDataKey` and `Decrypt`. But it cannot include other operations, such as `ScheduleKeyDeletion` or `ReEncrypt`.

Also, the [grant constraints](#) in child grants must be equally restrictive or more restrictive than those in the parent grant. For example, the child grant can add pairs to an `EncryptionContextSubset` constraint in the parent grant, but it cannot remove them. The child grant can change an `EncryptionContextSubset` constraint to an `EncryptionContextEquals` constraint, but not the reverse.

## Using Service-Linked Roles for AWS KMS

AWS Key Management Service uses AWS Identity and Access Management (IAM) [service-linked roles](#). A service-linked role is a unique type of IAM role that is linked directly to AWS KMS. Service-linked roles are

defined by AWS KMS and include all the permissions that the service requires to call other AWS services on your behalf.

A service-linked role makes setting up AWS KMS easier because you don't have to manually add the necessary permissions. AWS KMS defines the permissions of its service-linked roles, and unless defined otherwise, only AWS KMS can assume its roles. The defined permissions include the trust policy and the permissions policy, and that permissions policy cannot be attached to any other IAM entity.

You can delete a service-linked role only after first deleting the related resources. This protects your AWS KMS resources because you can't inadvertently remove permission to access the resources.

For information about other services that support service-linked roles, see [AWS Services That Work with IAM](#) and look for the services that have **Yes** in the **Service-Linked Role** column. Choose a **Yes** with a link to view the service-linked role documentation for that service.

## Service-Linked Role Permissions for AWS KMS Custom Key Stores

AWS KMS uses a service-linked role named **AWSServiceRoleForKeyManagementServiceCustomKeyStores** to support [custom key stores \(p. 172\)](#). This service-linked role gives AWS KMS permission to view your AWS CloudHSM clusters and create the network infrastructure to support a connection between your custom key store and its AWS CloudHSM cluster. AWS KMS creates this role only when you create a [custom key store \(p. 172\)](#). You cannot create this service-linked role directly.

The **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role trusts `cks.kms.amazonaws.com` to assume the role. As a result, only AWS KMS can assume this service-linked role.

The permissions in the role are limited to the actions that AWS KMS performs to connect a custom key store to an AWS CloudHSM cluster. It does not give AWS KMS any additional permissions. For example, AWS KMS does not have permission to create, manage, or delete your AWS CloudHSM clusters, HSMs, or backups.

For more information about the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** role, including a list of permissions and instructions for how to view the role, edit the role description, delete the role, and have AWS KMS recreate it for you, see [Authorizing AWS KMS to Manage AWS CloudHSM and Amazon EC2 Resources \(p. 177\)](#).

## Determining Access to an AWS KMS Customer Master Key

To determine the full extent of who or what currently has access to a customer master key (CMK) in AWS KMS, you must examine the CMK's key policy, all [grants \(p. 115\)](#) that apply to the CMK, and potentially all AWS Identity and Access Management (IAM) policies. You might do this to determine the scope of potential usage of a CMK, or to help you meet compliance or auditing requirements. The following topics can help you generate a complete list of the AWS principals (identities) that currently have access to a CMK.

### Topics

- [Examining the Key Policy \(p. 119\)](#)
- [Examining IAM Policies \(p. 121\)](#)
- [Examining Grants \(p. 122\)](#)
- [Troubleshooting Key Access \(p. 123\)](#)

## Examining the Key Policy

[Key policies \(p. 50\)](#) are the primary way to control access to AWS KMS customer master keys (CMKs).

When a key policy consists of or includes the [default key policy \(p. 52\)](#), the key policy allows IAM administrators in the account to use IAM policies to control access to the CMK. Also, if the key policy gives [another AWS account \(p. 71\)](#) permission to use the CMK, the IAM administrators in the external account can use IAM policies to delegate those permissions. To determine the complete list of principals that can access the CMK, [examine IAM the policies \(p. 121\)](#).

To view the key policy of an AWS KMS [customer managed CMK \(p. 3\)](#) or [AWS managed CMK \(p. 4\)](#) in your account, use the AWS Management Console or the [GetKeyPolicy](#) operation in the AWS KMS API. To view the key policy, you must have `kms:GetKeyPolicy` permissions for the CMK. For instructions for viewing the key policy for a CMK, see [the section called "Viewing a Key Policy" \(p. 61\)](#).

Examine the key policy document and take note of all principals specified in each policy statement's `Principal` element. The IAM users, IAM roles, and AWS accounts in the `Principal` elements are those that have access to this CMK.

### Note

Do not set the `Principal` to an asterisk (\*) in any key policy statement that allows permissions. An asterisk gives every identity in every AWS account permission to use the CMK, unless another policy statement explicitly denies it. Users in other AWS accounts just need corresponding IAM permissions in their own accounts to use the CMK.

The following examples use the policy statements found in the [default key policy \(p. 51\)](#) to demonstrate how to do this.

### Example Policy Statement 1

```
{
  "Sid": "Enable IAM User Permissions",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:root"},
  "Action": "kms:*",
  "Resource": "*"
}
```

In the preceding policy statement, `arn:aws:iam::111122223333:root` refers to the AWS account 111122223333. By default, a policy statement like this one is present in the key policy document when you create a new CMK with the console. It is also present when you create a new CMK programmatically but do not provide a key policy.

A key policy document with a statement that allows access to the AWS account (root user) enables [IAM policies in the account to allow access to the CMK \(p. 52\)](#). This means that IAM users and roles in the account might have access to the CMK even if they are not explicitly listed as principals in the key policy document. Take care to [examine all IAM policies \(p. 121\)](#) in all AWS accounts listed as principals to determine whether they allow access to this CMK.

### Example Policy Statement 2

```
{
  "Sid": "Allow access for Key Administrators",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:user/KMSKeyAdmin"},
  "Action": [
    "kms:Describe*",
    "kms:Put*",
    "kms:Create*",
    "kms:Update*",
    "kms:Enable*"
  ]
}
```

```
"kms:Revoke*",
"kms:List*",
"kms:Disable*",
"kms:Get*",
"kms>Delete*",
"kms:ScheduleKeyDeletion",
"kms:CancelKeyDeletion"
],
"Resource": "*"
}
```

In the preceding policy statement, `arn:aws:iam::111122223333:user/KMSKeyAdmin` refers to the IAM user named `KMSKeyAdmin` in AWS account `111122223333`. This user is allowed to perform the actions listed in the policy statement, which are the administrative actions for managing a CMK.

### Example Policy Statement 3

```
{
  "Sid": "Allow use of the key",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:role/EncryptionApp"},
  "Action": [
    "kms:DescribeKey",
    "kms:GenerateDataKey*",
    "kms:Encrypt",
    "kms:ReEncrypt*",
    "kms:Decrypt"
  ],
  "Resource": "*"
}
```

In the preceding policy statement, `arn:aws:iam::111122223333:role/EncryptionApp` refers to the IAM role named `EncryptionApp` in AWS account `111122223333`. Principals that can assume this role are allowed to perform the actions listed in the policy statement, which are the cryptographic actions for encrypting and decrypting data with a CMK.

### Example Policy Statement 4

```
{
  "Sid": "Allow attachment of persistent resources",
  "Effect": "Allow",
  "Principal": {"AWS": "arn:aws:iam::111122223333:role/EncryptionApp"},
  "Action": [
    "kms:ListGrants",
    "kms:CreateGrant",
    "kms:RevokeGrant"
  ],
  "Resource": "*",
  "Condition": {"Bool": {"kms:GrantIsForAWSResource": true}}
}
```

In the preceding policy statement, `arn:aws:iam::111122223333:role/EncryptionApp` refers to the IAM role named `EncryptionApp` in AWS account `111122223333`. Principals that can assume this role are allowed to perform the actions listed in the policy statement. These actions, when combined with the actions allowed in **Example policy statement 3**, are those necessary to delegate use of the CMK to most [AWS services that integrate with AWS KMS \(p. 228\)](#), specifically the services that use [grants \(p. 115\)](#). The `Condition` element ensures that the delegation is allowed only when the delegate is an AWS service that integrates with AWS KMS and uses grants for authorization.

To learn all the different ways you can specify a principal in a key policy document, see [Specifying a Principal](#) in the *IAM User Guide*.

To learn more about AWS KMS key policies, see [Using Key Policies in AWS KMS \(p. 50\)](#).

## Examining IAM Policies

In addition to the key policy and grants, you can also use IAM policies in combination with a CMK's key policy to allow access to a CMK. For more information about how IAM policies and key policies work together, see [Troubleshooting Key Access \(p. 123\)](#).

To determine which principals currently have access to a CMK through IAM policies, you can use the browser-based [IAM Policy Simulator](#) tool, or you can make requests to the IAM API.

### Ways to examine IAM policies

- [Examining IAM Policies with the IAM Policy Simulator \(p. 121\)](#)
- [Examining IAM Policies with the IAM API \(p. 121\)](#)

## Examining IAM Policies with the IAM Policy Simulator

The IAM Policy Simulator can help you learn which principals have access to a KMS CMK through an IAM policy.

### To use the IAM Policy Simulator to determine access to a KMS CMK

1. Sign in to the AWS Management Console and then open the IAM Policy Simulator at <https://policysim.aws.amazon.com/>.
2. In the **Users, Groups, and Roles** pane, choose the user, group, or role whose policies you want to simulate.
3. (Optional) Clear the check box next to any policies that you want to omit from the simulation. To simulate all policies, leave all policies selected.
4. In the **Policy Simulator** pane, do the following:
  - a. For **Select service**, choose **Key Management Service**.
  - b. To simulate specific AWS KMS actions, for **Select actions**, choose the actions to simulate. To simulate all AWS KMS actions, choose **Select All**.
5. (Optional) The Policy Simulator simulates access to all KMS CMKs by default. To simulate access to a specific KMS CMK, choose **Simulation Settings** and then type the Amazon Resource Name (ARN) of the KMS CMK to simulate.
6. Choose **Run Simulation**.

You can view the results of the simulation in the **Results** section. Repeat steps 2 through 6 for every IAM user, group, and role in the AWS account.

## Examining IAM Policies with the IAM API

You can use the IAM API to examine IAM policies programmatically. The following steps provide a general overview of how to do this:

1. For each AWS account listed as a principal in the CMK's key policy (that is, each *root account* listed in this format: "Principal": {"AWS": "arn:aws:iam::111122223333:root"}), use the [ListUsers](#) and [ListRoles](#) operations in the IAM API to retrieve a list of every IAM user and role in the account.
2. For each IAM user and role in the list, use the [SimulatePrincipalPolicy](#) operation in the IAM API, passing in the following parameters:
  - For `PolicySourceArn`, specify the Amazon Resource Name (ARN) of a user or role from your list. You can specify only one `PolicySourceArn` for each `SimulatePrincipalPolicy` request, so you must call this operation multiple times, once for each IAM user and role in your list.

- For the `ActionNames` list, specify every AWS KMS API action to simulate. To simulate all AWS KMS API actions, use `kms:*`. To test individual AWS KMS API actions, precede each API action with `"kms:"`, for example `"kms:ListKeys"`. For a complete list of all AWS KMS API actions, see [Actions](#) in the *AWS Key Management Service API Reference*.
- (Optional) To determine whether the IAM users or roles have access to specific KMS CMKs, use the `ResourceArns` parameter to specify a list of the Amazon Resource Names (ARNs) of the CMKs. To determine whether the IAM users or roles have access to any CMK, do not use the `ResourceArns` parameter.

IAM responds to each `SimulatePrincipalPolicy` request with an evaluation decision: `allowed`, `explicitDeny`, or `implicitDeny`. For each response that contains an evaluation decision of `allowed`, the response includes the name of the specific AWS KMS API operation that is allowed. It also includes the ARN of the CMK that was used in the evaluation, if any.

## Examining Grants

Grants are advanced mechanisms for specifying permissions that you or an AWS service integrated with AWS KMS can use to specify how and when a CMK can be used. Grants are attached to a CMK, and each grant contains the principal who receives permission to use the CMK and a list of operations that are allowed. Grants are an alternative to the key policy, and are useful for specific use cases. For more information, see [Using Grants \(p. 115\)](#).

To get a list of grants for a CMK, use the AWS KMS [ListGrants](#) operation. You can examine the grants for a CMK to determine who or what currently has access to use the CMK via those grants. For example, the following is a JSON representation of a grant that was obtained from the `list-grants` command in the AWS CLI.

```
{
  "Grants": [
    {
      "Operations": [
        "Decrypt"
      ],
      "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "Name": "0d8aa621-43ef-4657-b29c-3752c41dc132",
      "RetiringPrincipal": "arn:aws:iam::123456789012:root",
      "GranteePrincipal": "arn:aws:sts::111122223333:assumed-role/aws-ec2-infrastructure/i-5d476fab",
      "GrantId": "dc716f53c93acacf291b1540de3e5a232b76256c83b2ecb22cdefa26576a2d3e",
      "IssuingAccount": "arn:aws:iam::111122223333:root",
      "CreationDate": 1.444151834E9,
      "Constraints": {
        "EncryptionContextSubset": {
          "aws:ebs:id": "vol-5cccfb4e"
        }
      }
    }
  ]
}
```

To find out who or what has access to use the CMK, look for the `"GranteePrincipal"` element. In the preceding example, the grantee principal is an assumed role user that is associated with the EC2 instance `i-5d476fab`. The EC2 infrastructure uses this role to attach the encrypted EBS volume `vol-5cccfb4e` to the instance. In this case, the EC2 infrastructure role has permission to use the CMK because you previously created an encrypted EBS volume that is protected by this CMK. You then attached the volume to an EC2 instance.

The following is another example of a JSON representation of a grant that was obtained from the `list-grants` command in the AWS CLI. In the following example, the grantee principal is another AWS account.

```
{
  "Grants": [
    {
      "Operations": [
        "Encrypt"
      ],
      "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "Name": "",
      "GranteePrincipal": "arn:aws:iam::444455556666:root",
      "GrantId": "f271e8328717f8bde5d03f4981f06a6b3fc18bcae2da12ac38bd9186e7925d11",
      "IssuingAccount": "arn:aws:iam::111122223333:root",
      "CreationDate": 1.444151269E9
    }
  ]
}
```

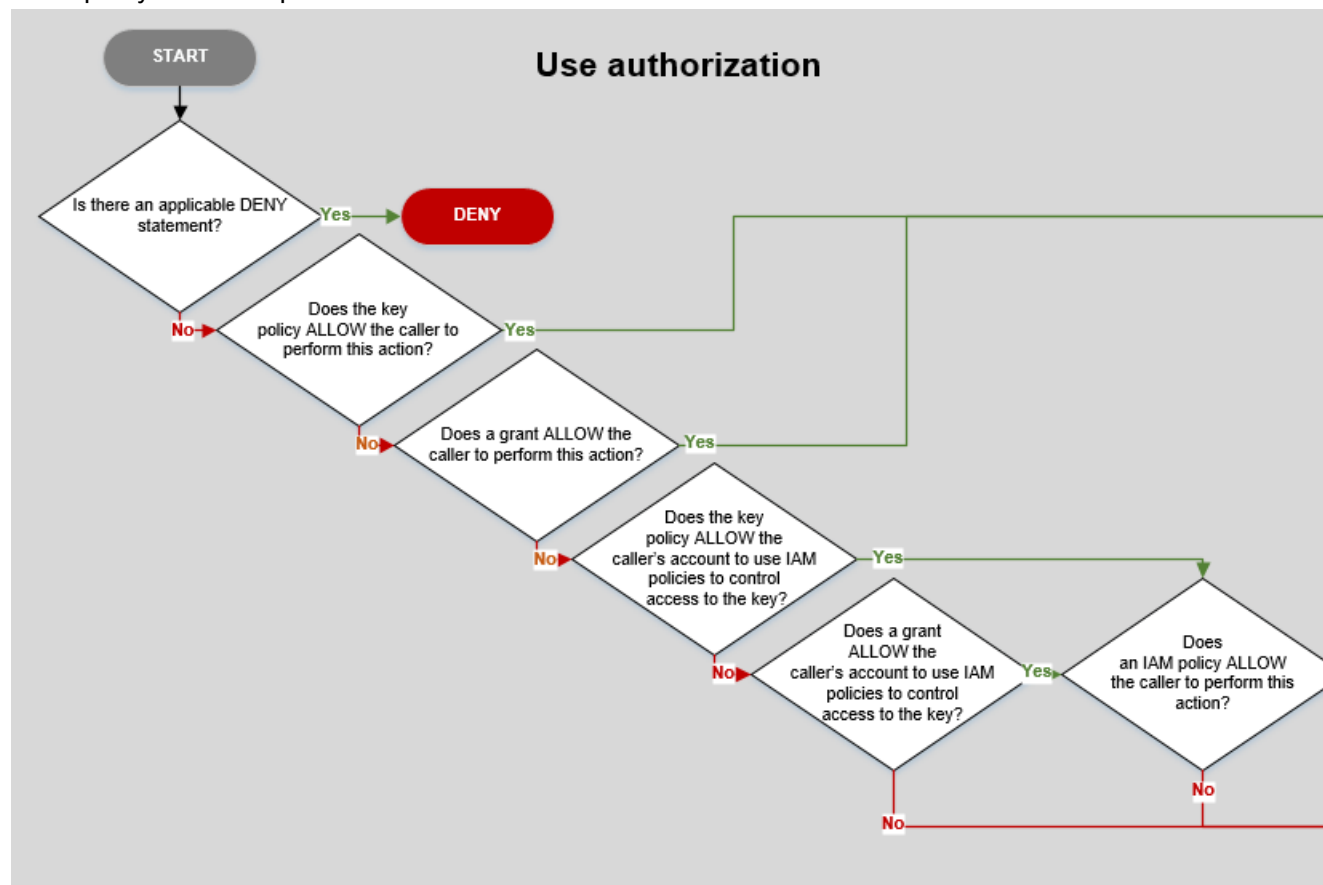

}}}

## Troubleshooting Key Access

When authorizing access to a customer master key (CMK), AWS KMS evaluates the following:

- The key policy that is attached to the CMK. The key policy is always defined in the AWS account that owns the CMK.
- All IAM policies that are attached to the IAM user or role making the request. IAM policies that govern a principal's use of a CMK are always defined in the principal's AWS account.
- All grants that apply to the CMK.

AWS KMS evaluates the CMK's [key policy \(p. 119\)](#), [IAM policies \(p. 121\)](#), and [grants \(p. 122\)](#) together to determine whether access to the CMK is allowed or denied. To do this, AWS KMS uses a process similar to the one depicted in the following flowchart. The following flowchart provides a visual representation of the policy evaluation process.

This flowchart is divided into two parts. The parts appear to be sequential, but they are typically evaluated at the same time.

- *Use authorization* determines whether you are permitted to use a CMK based on its key policy, IAM policies, and grants.
- *Key trust* determines whether you should trust a CMK that you are permitted to use. In general, you trust the resources in your AWS account. But, you can also feel confident about using CMKs in a different AWS account if a grant or IAM policy in your account allows you to use the CMK.

You can use this flowchart to discover why a caller was allowed or denied permission to use a CMK. You can also use it to evaluate your policies and grants. For example, the flowchart shows that a caller can be denied access by an explicit **DENY** statement, or by the absence of an explicit **ALLOW** statement, in the key policy, IAM policy, or grant.

The flowchart can explain some common permission scenarios.

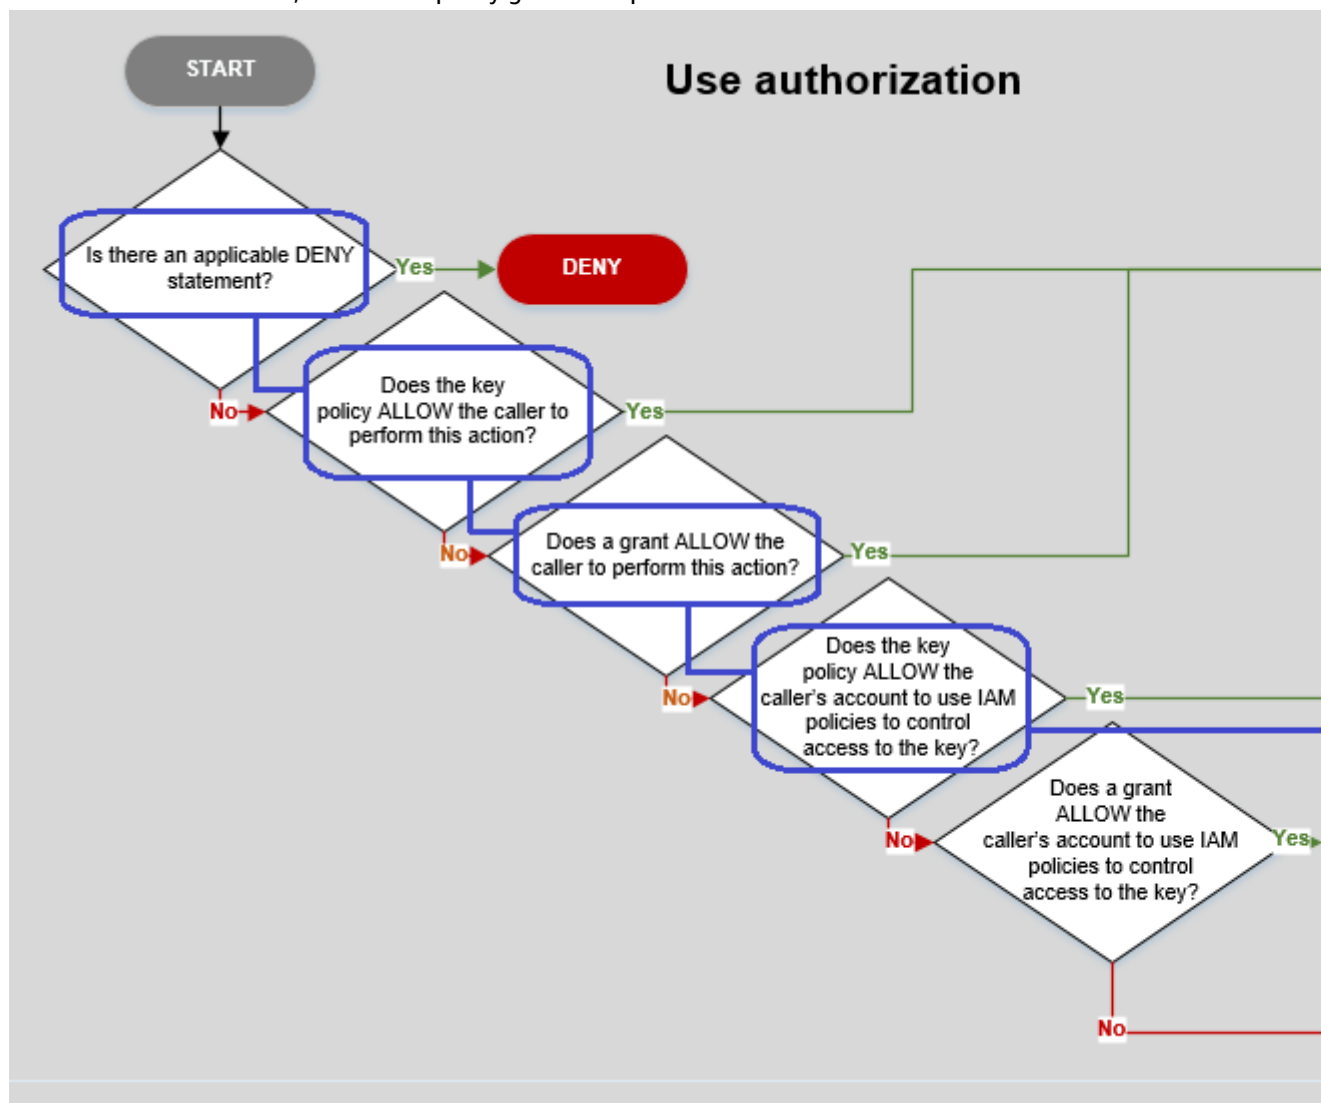

#### Permission Examples

- [Example 1: User Is Denied Access to a CMK in Their AWS Account \(p. 124\)](#)
- [Example 2: User Assumes Role with Permission to Use a CMK in a Different AWS Account \(p. 125\)](#)

## Example 1: User Is Denied Access to a CMK in Their AWS Account

Alice is an IAM user in the 111122223333 AWS account. She was denied access to a CMK in same AWS account. Why can't Alice use the CMK?

In this case, Alice is denied access to the CMK because there is no key policy, IAM policy, or grant that gives her the required permissions. The CMK's key policy allows the AWS account to use IAM policies to control access to the CMK, but no IAM policy gives Alice permission to use the CMK.

Consider the relevant policies for this example.

- The CMK that Alice wants to use has the [default key policy \(p. 51\)](#). This policy [allows the AWS account \(p. 52\)](#) that owns the CMK to use IAM policies to control access to the CMK. This key policy satisfies the *Does the key policy ALLOW the callers account to use IAM policies to control access to the key?* condition in the flowchart.

```
{
  "Version" : "2012-10-17",
  "Id" : "key-test-1",
  "Statement" : [ {
    "Sid" : "Delegate to IAM policies",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::111122223333:root"
    },
    "Action" : "kms:*",
    "Resource" : "*"
  } ]
}
```

- However, no key policy, IAM policy, or grant gives Alice permission to use the CMK. Therefore, Alice is denied permission to use the CMK.

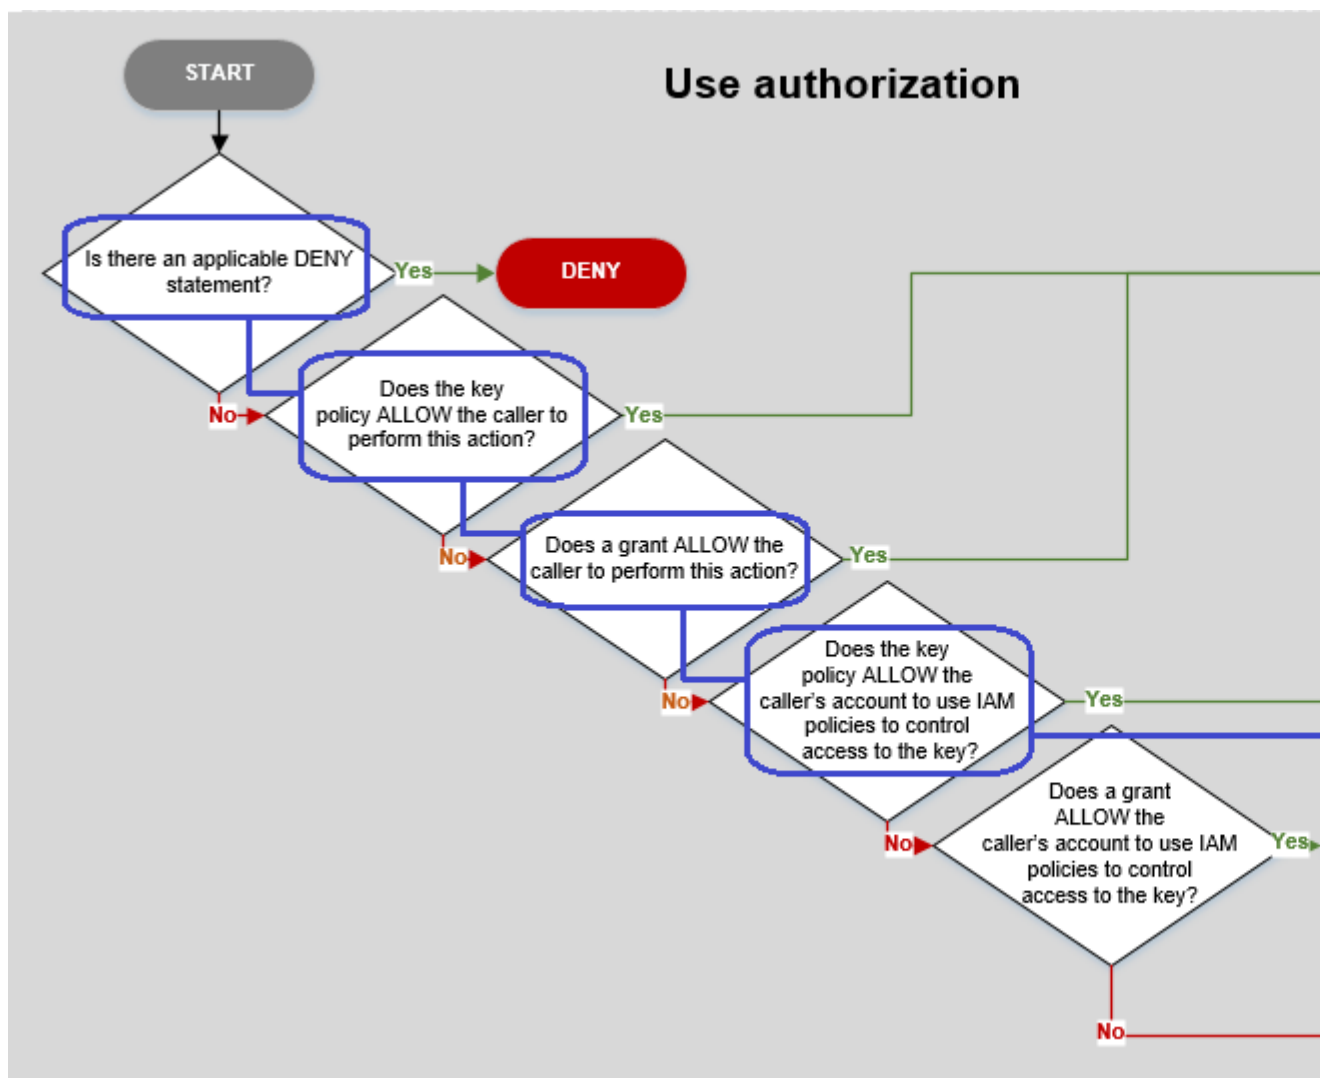

## Example 2: User Assumes Role with Permission to Use a CMK in a Different AWS Account

Bob is a user in account 1 (111122223333). He is allowed to use a CMK in account 2 (444455556666) in cryptographic operations. How is this possible?

### Tip

When evaluating cross-account permissions, remember that the key policy is specified in the CMK's account. The IAM policy is specified in the caller's account, even when the caller is in a different account.

- The key policy for the CMK in account 2 allows account 2 to use IAM policies to control access to the CMK.
- The key policy for the CMK in account 2 allows account 1 to use the CMK in cryptographic operations. However, account 1 must use IAM policies to give its principals access to the CMK.
- An IAM policy in account 1 allows the `ExampleRole` role to use the CMK in account 2 for cryptographic operations.
- Bob, a user in account 1, has permission to assume the `ExampleRole` role.
- Bob can trust this CMK, because even though it is not in his account, an IAM policy in his account gives him explicit permission to use this CMK.

Consider the policies that let Bob, a user in account 1, use the CMK in account 2.

- The key policy for the CMK allows account 2 (444455556666, the account that owns the CMK) to use IAM policies to control access to the CMK. This key policy also allows account 1 (111122223333) to use the CMK in cryptographic operations (specified in the `Action` element of the policy statement). However, no one in account 1 can use the CMK in account 2 until account 1 defines IAM policies that give the principals access to the CMK.

In the flowchart, this key policy in account 2 satisfies the *Does the key policy ALLOW the caller's account to use IAM policies to control access to the key?* condition.

```
{
  "Id": "key-policy-acct-2",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Permission to use IAM policies",
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::444455556666:root"
      },
    },
  ],
}
```

```

        "Action": "kms:*",
        "Resource": "*"
    },
    {
        "Sid": "Allow account 1 to use this CMK",
        "Effect": "Allow",
        "Principal": {
            "AWS": "arn:aws:iam::111122223333:root"
        },
        "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncryptFrom",
            "kms:ReEncryptTo",
            "kms:GenerateDataKey",
            "kms:GenerateDataKeyWithoutPlaintext",
            "kms:DescribeKey"
        ],
        "Resource": "*"
    }
]
}

```

- An IAM policy in the caller's AWS account (account 1, 111122223333) gives the `ExampleRole` role in account 1 permission to perform cryptographic operations using the CMK in account 2 (444455556666). The `Action` element gives the role the same permissions that the key policy in account 2 gave to account 1.

Cross-account IAM policies like this one are effective only when the key policy for the CMK in account 2 gives account 1 permission to use the CMK. Also, account 1 can only give its principals permission to perform the actions that the key policy gave to the account.

In the flowchart, this satisfies the *Does an IAM policy allow the caller to perform this action?* condition.

```

{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Principal": { "arn:aws:iam::111122223333:role/ExampleRole" },
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt",
        "kms:Decrypt",
        "kms:ReEncryptFrom",
        "kms:ReEncryptTo",
        "kms:GenerateDataKey",
        "kms:GenerateDataKeyWithoutPlaintext",
        "kms:DescribeKey"
      ],
      "Resource": [
        "arn:aws:kms:us-west-2:444455556666:key/1234abcd-12ab-34cd-56ef-1234567890ab"
      ]
    }
  ]
}

```

- The last required element is the definition of the `ExampleRole` role in account 1. The `AssumeRolePolicyDocument` in the role allows Bob to assume the `ExampleRole` role.

```

{
  "Role": {
    "Arn": "arn:aws:iam::111122223333:role/ExampleRole",

```

```
"CreateDate": "2019-05-16T00:09:25Z",
"AssumeRolePolicyDocument": {
  "Version": "2012-10-17",
  "Statement": {
    "Principal": {
      "AWS": "arn:aws:iam::111122223333:user/bob"
    },
    "Effect": "Allow",
    "Action": "sts:AssumeRole"
  }
},
"Path": "/",
"RoleName": "ExampleRole",
"RoleId": "AROA4KJY2TU23Y7NK62MV"
}
```

# Using Symmetric and Asymmetric Keys

AWS KMS protects the [customer master keys \(p. 2\)](#) (CMKs) that you use to protect your data and data keys. Your secret keys are generated and used only in hardware security modules designed so that no one, including AWS employees, can access the plaintext key material.

You can create and manage the CMKs in your AWS account, including setting the [key policies \(p. 50\)](#), [IAM policies \(p. 67\)](#), and [grants \(p. 115\)](#) that control access to your CMKs, enabling and disabling the CMKs, creating tags and aliases, and deleting the CMKs. You can use your CMKs to protect your resources in [AWS services that are integrated with AWS KMS \(p. 228\)](#). And, you can audit all operations that use or manage your CMKs in [AWS CloudTrail logs \(p. 293\)](#).

AWS KMS supports symmetric and asymmetric CMKs.

- [Symmetric CMK \(p. 130\)](#): Represents a single 256-bit secret encryption key that never leaves AWS KMS unencrypted. To use your symmetric CMK, you must call AWS KMS.
- [Asymmetric CMK \(p. 130\)](#): Represents a mathematically related public key and private key pair that you can use for encryption and decryption or signing and verification, but not both. The private key never leaves AWS KMS unencrypted. You can use the public key within AWS KMS by calling the AWS KMS API operations, or download the public key and use it outside of AWS KMS.

## Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

AWS KMS also provides symmetric [data keys \(p. 4\)](#) and asymmetric [data key pairs \(p. 6\)](#) that are designed to be used for client-side cryptography outside of AWS KMS. The symmetric data key and the private key in an asymmetric data key pair are protected by a symmetric CMK in AWS KMS.

- Symmetric data key — A symmetric encryption key that you can use to encrypt data outside of AWS KMS. This key is protected by a symmetric CMK in AWS KMS.
- Asymmetric data key pair — An RSA or elliptic curve (ECC) key pair that consists of a public key and a private key. You can use your data key pair outside of AWS KMS to encrypt and decrypt data, or sign messages and verify signatures. The private key is protected by a symmetric CMK in AWS KMS.

For information about how to create and use data keys and data key pairs, see [Data Keys \(p. 4\)](#) and [Data Key Pairs \(p. 6\)](#). To learn how to limit the types of data key pairs that principals in your account are permitted to generate, use the [kms:DataKeyPairSpec \(p. 93\)](#) condition key.

This topic explains how symmetric and asymmetric CMKs work, how they differ, and how to decide which type of CMK you need to protect your data. It also explains how symmetric data keys and asymmetric data key pairs work and how to use them outside of AWS KMS.

## Learn more

- For a table that compares the AWS KMS API operations that apply to each type of CMK, see [the section called “Comparing Symmetric and Asymmetric CMKs” \(p. 138\)](#).

- To find out whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs](#) (p. 33).
- To examine the difference in the default key policy that the AWS KMS console sets for symmetric and asymmetric CMKs, see [the section called “Allows Key Users to Use the CMK with AWS Services”](#) (p. 57).
- To specify the key specs, key usage, encryption algorithms, and signing algorithms that principals in your account can use for CMKs, see [the section called “AWS KMS Condition Keys”](#) (p. 88).
- To learn about the request quotas that apply to different types of CMKs, see [the section called “Request Quotas”](#) (p. 355).
- To learn how to sign messages and verify signatures with asymmetric CMKs, see [Digital signing with the new asymmetric keys feature of AWS KMS](#) in the *AWS Security Blog*.

#### Topics

- [About Symmetric and Asymmetric CMKs](#) (p. 130)

- [Viewing the Cryptographic Configuration of CMKs](#) (p. 137)
- [Comparing Symmetric and Asymmetric CMKs](#) (p. 138)

## About Symmetric and Asymmetric CMKs

In AWS KMS, you can create symmetric and asymmetric CMKs.

### Symmetric Customer Master Keys

When you create a customer master key (CMK) in KMS, by default, you get a symmetric CMK.

In AWS KMS, a *symmetric CMK* represents a 256-bit encryption key that never leaves AWS KMS unencrypted. To use a symmetric CMK, you must call AWS KMS. Symmetric keys are used in symmetric encryption, where the same key is used for encryption and decryption.

Unless your task explicitly requires asymmetric encryption, symmetric CMKs, which never leave AWS KMS unencrypted, are a good choice. For information about the cryptographic configuration or *key spec* for symmetric CMKs, see [SYMMETRIC\\_DEFAULT Key Spec](#) (p. 134). For help creating a symmetric CMK, see [Creating Symmetric CMKs](#) (p. 17).

[AWS services that are integrated with AWS KMS](#) use symmetric CMKs to protect your data. These services do not support asymmetric CMKs. For help determining whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs](#) (p. 33).

You can use a symmetric CMK in AWS KMS to encrypt, decrypt, and re-encrypt data, generate data keys and data key pairs, and generate random byte strings. You can [import your own key material](#) (p. 147) into a symmetric CMK and create symmetric CMKs in [custom key stores](#) (p. 172). For a table comparing the operations that you can perform on symmetric and asymmetric CMKs, see [Comparing Symmetric and Asymmetric CMKs](#) (p. 138).

### Asymmetric Customer Master Keys

#### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

You can create an asymmetric CMK in AWS KMS. An *asymmetric CMK* represents a mathematically related public key and private key pair. You can give the public key to anyone, even if they're not trusted, but the private key must be kept secret.

In an asymmetric CMK, the private key is created in AWS KMS and never leaves AWS KMS unencrypted. To use the private key, you must call AWS KMS. You can use the public key within AWS KMS by calling the AWS KMS API operations. Or, you can [download the public key \(p. 43\)](#) and use it outside of AWS KMS.

If your use case requires encryption outside of AWS by users who cannot call AWS KMS, asymmetric CMKs are a good choice. However, if you are creating a CMK to encrypt the data that you store or manage in an AWS service, use a symmetric CMK. AWS services that integrate with AWS KMS do not support asymmetric CMKs.

AWS KMS supports two types of asymmetric CMKs.

- **RSA CMKs:** A CMK with an RSA key pair for encryption and decryption or signing and verification (but not both). KMS supports several key lengths for different security requirements.
- **Elliptic Curve (ECC) CMKs:** A CMK with an elliptic curve key pair for signing and verification. KMS supports several commonly-used curves.

For technical details about the encryption and signing algorithms that AWS KMS supports for RSA CMKs, see [RSA Key Specs \(p. 134\)](#). For technical details about the signing algorithms that AWS KMS supports for ECC CMKs, see [Elliptic Curve Key Specs \(p. 136\)](#).

For a table comparing the operations that you can perform on symmetric and asymmetric CMKs, see [Comparing Symmetric and Asymmetric CMKs \(p. 138\)](#). For help determining whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

## How to Choose Your CMK Configuration

The type of CMK that you create depends largely on how you plan to use the CMK, your security requirements, and your authorization requirements. When creating your CMK, remember that the cryptographic configuration of the CMK, including its key spec and key usage are established when you create the CMK and cannot be changed. For help with creating symmetric and asymmetric CMK, see [the section called “Creating Keys” \(p. 17\)](#).

AWS KMS supports two CMK key types: **Symmetric** and **Asymmetric**. Each key type is associated with particular [key usage \(p. 132\)](#) and [key spec \(p. 133\)](#) options.

Use the following guidance to determine which type of CMK you need based on your use case.

### Encrypt and decrypt data

Use a [symmetric CMK \(p. 130\)](#) for most use cases that require encrypting and decrypting data. The symmetric encryption algorithm that AWS KMS uses is fast, efficient, and assures the confidentiality and authenticity of data. It supports authenticated encryption with additional authenticated data (AAD), defined as an [encryption context \(p. 12\)](#). This type of CMK requires both the sender and recipient of encrypted data to have valid AWS credentials to call AWS KMS.

If your use case requires encryption outside of AWS by users who cannot call AWS KMS, [asymmetric CMKs \(p. 130\)](#) are a good choice. You can distribute the public portion of the asymmetric CMK to allow these users to encrypt data. And your applications that need to decrypt that data can use the private portion of the asymmetric CMK within AWS KMS.

### Sign messages and verify signatures

To sign messages and verify signatures, you must use an [asymmetric CMK \(p. 130\)](#). You can use a CMK with a [key spec \(p. 133\)](#) that represents an RSA key pair or an elliptic curve (ECC) key pair. The key spec you choose is determined by the signing algorithm that you want to use. In some cases, the users who will verify signatures are outside of AWS and can't call the [Verify](#) operation. In that case, [choose a key spec \(p. 133\)](#) associated with a signing algorithm that these users can support in their local applications.

## Perform public key encryption

To perform public key encryption, you must use an [asymmetric CMK \(p. 130\)](#) with an [RSA key spec \(p. 135\)](#). [Elliptic curve \(ECC\) key specs \(p. 136\)](#) cannot be used for public key encryption. To encrypt data in AWS KMS with the public key of an RSA CMK, use the [Encrypt](#) operation. You can also [download the public key \(p. 43\)](#) and share it with the parties that need to encrypt data outside of AWS KMS.

When you download the public key of an asymmetric CMK, you can use it outside of AWS KMS. But it is no longer subject to the security controls that protect the CMK in AWS KMS. For example, you cannot use KMS key policies or grants to control use of the public key. Nor can you control whether the key is used only for encryption and decryption using the RSA encryption algorithms that AWS KMS supports. For more details, see [Special Considerations for Downloading Public Keys \(p. 43\)](#).

To decrypt data that was encrypted with the public key outside of AWS KMS, call the [Decrypt](#) operation. The [Decrypt](#) operation fails if the data was encrypted under a public key from a CMK with a [key usage \(p. 132\)](#) of `SIGN_VERIFY`. It will also fail if it was encrypted by using an algorithm that KMS does not support for RSA CMKs.

To avoid these errors, anyone using a public key outside of AWS KMS must store the key configuration. The AWS KMS console and the [GetPublicKey](#) response provide the information that you must include when you share the public key.

## Use with Integrated AWS Services

To create a CMK for use with an [AWS service that is integrated with AWS KMS \(p. 228\)](#), consult the documentation for the service. All AWS services that encrypt data on your behalf require a [symmetric CMK \(p. 130\)](#).

In addition to these considerations, CMKs with different key specs have different prices and different request quotas. For information about AWS KMS pricing, see [AWS Key Management Service Pricing](#). For information about request quotas, see [Request Quotas \(p. 355\)](#).

# Selecting the Key Usage

The *key usage* of a CMK determines whether the CMK is used for encryption and decryption -or- signing and verification. You cannot choose both. Using a CMK for more than one type of operations makes the product of both operations more vulnerable to attack.

As shown in the following table, symmetric CMKs can be used only for encryption and decryption. Elliptic curve (ECC) CMKs can be used only for signing and verification. Key usage decisions are really made only for RSA CMKs.

## Valid key usage for CMK types

CMK type	Encrypt and decrypt	Sign and Verify
Symmetric CMKs	✓	✗
Asymmetric CMKs with RSA key pairs	✓	✓
Asymmetric CMKs with ECC key pairs	✗	✓

In the AWS KMS console, you first choose the key type (symmetric or asymmetric), and then, for asymmetric CMKs, the key usage. If you select a symmetric key type, the key usage options do not

appear, because symmetric CMKs only support encryption and decryption. The key usage that you choose determines which [key specs \(p. 133\)](#) are displayed.

To choose a key usage in the AWS KMS console:

- For CMKs with elliptic curve (ECC) key material, choose **Sign and verify**.
- For CMKs with RSA key material, choose **Encrypt and decrypt** or **Sign and verify**.

To determine the key usage that principals in your account are permitted to use for CMKs, use the [kms:CustomerMasterKeyUsage \(p. 92\)](#) condition key.

## Selecting the Key Spec

When you create an asymmetric CMK, you select its key spec. The *key spec*, which is a property of every customer master key (CMK), represents the cryptographic configuration of your CMK. You choose the key spec when you create the CMK, and you cannot change it. If you've selected the wrong key spec, [delete the CMK \(p. 160\)](#), and create a new one.

### Note

In AWS KMS API operations, the key spec for CMKs is known as the `CustomerMasterKeySpec`. This distinguishes it from the key spec for data keys (`KeySpec`) and data key pairs (`KeyPairSpec`), and the key spec used when wrapping key material for import (`WrappingKeySpec`). Each key spec type has different values.

The key spec determines whether the CMK is symmetric or asymmetric, the type of key material in the CMK, and the encryption algorithms or signing algorithms that AWS KMS supports for the CMK. The key spec that you choose is typically determined by your use case and regulatory requirements.

To determine the key specs that principals in your account are permitted to use for CMKs, use the [kms:CustomerMasterKeySpec \(p. 91\)](#) condition key.

AWS KMS supports the following key specs for CMKs:

- [Symmetric CMKs \(p. 134\)](#) (default; encryption and decryption)
  - SYMMETRIC\_DEFAULT
- [RSA key specs \(p. 134\)](#) (encryption and decryption -or- signing and verification)
  - RSA\_2048
  - RSA\_3072
  - RSA\_4096
- [Elliptic curve key specs \(p. 136\)](#)
  - Asymmetric NIST-recommended [elliptic curve key pairs](#) (signing and verification)
    - ECC\_NIST\_P256 (secp256r1)
    - ECC\_NIST\_P384 (secp384r1)
    - ECC\_NIST\_P521 (secp521r1)
  - Other asymmetric elliptic curve key pairs (signing and verification)
    - ECC\_SECG\_P256K1 ([secp256k1](#)), commonly used for cryptocurrency.

### Topics

The following topics provide technical information about the key specs.

- [SYMMETRIC\\_DEFAULT Key Spec \(p. 134\)](#)
- [RSA Key Specs \(p. 134\)](#)
- [Elliptic Curve Key Specs \(p. 136\)](#)

## SYMMETRIC\_DEFAULT Key Spec

The default key spec, SYMMETRIC\_DEFAULT, is the key spec for symmetric CMKs. When you select the **Symmetric** key type in the AWS KMS console, it selects the SYMMETRIC\_DEFAULT key spec. In the [CreateKey](#) operation, if you don't specify a `CustomerMasterKeySpec` value, SYMMETRIC\_DEFAULT is selected. If you don't have a reason to use a different key spec, SYMMETRIC\_DEFAULT is a good choice.

The encryption algorithm for symmetric CMKs is also known as SYMMETRIC\_DEFAULT. Currently, this represents a symmetric algorithm based on [Advanced Encryption Standard](#) (AES) in [Galois Counter Mode](#) (GCM) with 256-bit keys, an industry standard for secure encryption. The ciphertext that this algorithm generates supports additional authenticated data (AAD), such as an [encryption context](#) (p. 12), and GCM provides an additional integrity check on the ciphertext. For technical details, see the [AWS Key Management Service Cryptographic Details](#) whitepaper.

Data encrypted under AES-256-GCM is protected now and in the future. Cryptographers consider this algorithm to be *quantum resistant*. Theoretical future, large-scale quantum computing attacks on ciphertexts created under 256-bit AES-GCM keys [reduce the effective security of the key to 128 bits](#). But, this security level is sufficient to make brute force attacks on AWS KMS ciphertexts infeasible.

You can use a symmetric CMK in AWS KMS to encrypt, decrypt, and re-encrypt data, and generate data keys and data key pairs. AWS services that are integrated with AWS KMS generally use symmetric CMKs to encrypt your data at rest. You can [import your own key material](#) (p. 147) into a symmetric CMK and create symmetric CMKs in [custom key stores](#) (p. 172). For a table comparing the operations that you can perform on symmetric and asymmetric CMKs, see [Comparing Symmetric and Asymmetric CMKs](#) (p. 138).

## RSA Key Specs

When you use an RSA key spec, AWS KMS creates an asymmetric CMK with an RSA key pair. The private key never leaves AWS KMS unencrypted. You can use the public key within AWS KMS, or download the public key for use outside of AWS KMS.

### Warning

When you encrypt data outside of AWS KMS, if you use a public key from a CMK is configured for signing and verification, or an encryption algorithm that is not supported by the CMK, or use a public key from a CMK that has been deleted from AWS KMS, you cannot decrypt the ciphertext. The data is unrecoverable.

In AWS KMS, you can use asymmetric CMKs with RSA key pairs for encryption and decryption, or signing and verification, but not both. This property, known as [key usage](#) (p. 132), is determined separately from the key spec, but you should make that decision before you select a key spec.

AWS KMS supports the following RSA key specs for encryption and decryption or signing and verification:

- RSA\_2048
- RSA\_3072
- RSA\_4096

RSA key specs differ by the length of the RSA key in bits. The RSA key spec that you choose might be determined by your security standards or the requirements of your task. In general, use the largest key that is practical and affordable for your task. CMKs with different RSA key specs are priced differently and are subject to different request quotas. For information about AWS KMS pricing, see [AWS Key Management Service Pricing](#). For information about request quotas, see [Request Quotas](#) (p. 355).

## RSA Key Specs For Encryption and Decryption

When an RSA asymmetric CMK is used for encryption and decryption, you encrypt with the public key and decrypt with the private key. When you call the `Encrypt` operation in AWS KMS for an RSA CMK, AWS KMS uses the public key in the RSA key pair and the encryption algorithm you specify to encrypt your data. To decrypt the ciphertext, call the `Decrypt` operation and specify the same CMK and encryption algorithm. AWS KMS then uses the private key in the RSA key pair to decrypt your data.

You can also download the public key and use it to encrypt data outside of AWS KMS. Be sure to use an encryption algorithm that AWS KMS supports for RSA CMKs. To decrypt the ciphertext, call the `Decrypt` function with the same CMK and encryption algorithm.

AWS KMS supports two encryption algorithms for CMKs with RSA key specs. These algorithms, which are defined in [PKCS #1 v2.2](#), differ in the hash function they use internally. In AWS KMS, the `RSOAES_OAEP` algorithms always use the same hash function for both hashing purposes and for the [mask generation function](#) (MGF1). You are required to specify an encryption algorithm when you call the `Encrypt` and `Decrypt` operations. You can choose a different algorithm for each request.

### Supported encryption algorithms for RSA key specs

Encryption algorithm	Algorithm description
<code>RSOAES_OAEP_SHA_1</code>	PKCS #1 v2.2, Section 7.1. RSA encryption with OAEP Padding using SHA-1 for both the hash and in the MGF1 mask generation function along with an empty label.
<code>RSOAES_OAEP_SHA_256</code>	PKCS #1, Section 7.1. RSA encryption with OAEP Padding using SHA-256 for both the hash and in the MGF1 mask generation function along with an empty label.

You cannot configure a CMK to use a particular encryption algorithm. However, you can use the [kms:EncryptionAlgorithm](#) (p. 94) policy condition to specify the encryption algorithms that principals are allowed to use with the CMK.

To get the encryption algorithms for a CMK, [view the cryptographic configuration](#) (p. 25) of the CMK in the AWS KMS console or use the `DescribeKey` operation. AWS KMS also provides the key spec and encryption algorithms when you download your public key, either in the AWS KMS console or by using the `GetPublicKey` operation.

You might choose an RSA key spec based on the length of the plaintext data that you can encrypt in each request. The following table shows the maximum size, in bytes, of the plaintext that you can encrypt in a single call to the `Encrypt` operation. The values differ with the key spec and encryption algorithm. To compare, you can use a symmetric CMK to encrypt up to 4096 bytes at one time.

To compute the maximum plaintext length in bytes for these algorithms, use the following formula:  $(key\_size\_in\_bits / 8) - (2 * hash\_length\_in\_bits / 8) - 2$ . For example, for `RSA_2048` with `SHA-256`, the maximum plaintext size in bytes is  $(2048/8) - (2 * 256/8) - 2 = 190$ .

### Maximum plaintext size (in bytes) in an Encrypt operation

	Encryption algorithm	
<code>RSA_2048</code>	214	190
<code>RSA_3072</code>	342	318
<code>RSA_4096</code>	470	446

## RSA Key Specs For Signing and Verification

When an RSA asymmetric CMK is used for signing and verification, you generate the signature for a message with the private key and verify the signature with the public key.

When you call the `Sign` operation in AWS KMS for an asymmetric CMK, AWS KMS uses the private key in the RSA key pair, the message, and the signing algorithm you specify, to generate a signature. To verify the signature, call the `Verify` operation. Specify the signature, plus the same CMK, message, and signing algorithm. AWS KMS then uses the public key in the RSA key pair to verify the signature. You can also download the public key and use it to verify the signature outside of AWS KMS.

AWS KMS supports the following signing algorithms for CMKs with RSA key spec. You are required to specify an signing algorithm when you call the `Sign` and `Verify` operations. You can choose a different algorithm for each request.

### Supported signing algorithms for RSA key specs

Signing algorithm	Algorithm description
RSASSA_PKCS1_V1_5_SHA_256	PKCS #1 v2.2, Section 8.2, RSA signature with PKCS #1v1.5 Padding and SHA-256
RSASSA_PKCS1_V1_5_SHA_384	PKCS #1 v2.2, Section 8.2, RSA signature with PKCS #1v1.5 Padding and SHA-384
RSASSA_PKCS1_V1_5_SHA_512	PKCS #1 v2.2, Section 8.2, RSA signature with PKCS #1v1.5 Padding and SHA-512
RSASSA_PSS_SHA_256	PKCS #1 v2.2, Section 8.1, RSA signature with PSS padding using SHA-256 for both the message digest and the MGF1 mask generation function along with a 256-bit salt
RSASSA_PSS_SHA_384	PKCS #1 v2.2, Section 8.1, RSA signature with PSS padding using SHA-384 for both the message digest and the MGF1 mask generation function along with a 384-bit salt
RSASSA_PSS_SHA_512	PKCS #1 v2.2, Section 8.1, RSA signature with PSS padding using SHA-512 for both the message digest and the MGF1 mask generation function along with a 512-bit salt

You cannot configure a CMK to use particular signing algorithms. However, you can use the [kms:SigningAlgorithm \(p. 109\)](#) policy condition to specify the signing algorithms that principals are allowed to use with the CMK.

To get the signing algorithms for a CMK, [view the cryptographic configuration \(p. 25\)](#) of the CMK in the AWS KMS console or by using the `DescribeKey` operation. AWS KMS also provides the key spec and signing algorithms when you download your public key, either in the AWS KMS console or by using the `GetPublicKey` operation.

## Elliptic Curve Key Specs

When you use an elliptic curve (ECC) key spec, AWS KMS creates an asymmetric CMK with an ECC key pair for signing and verification. The private key that generates signature never leaves AWS KMS unencrypted. You can use the public key to [verify signatures](#) within AWS KMS, or [download the public key \(p. 152\)](#) for use outside of AWS KMS.

AWS KMS supports the following ECC key specs for asymmetric CMKs.

- Asymmetric NIST-recommended elliptic curve key pairs (signing and verification)
  - ECC\_NIST\_P256 (secp256r1)
  - ECC\_NIST\_P384 (secp384r1)
  - ECC\_NIST\_P521 (secp521r1)
- Other asymmetric elliptic curve key pairs (signing and verification)
  - ECC\_SECG\_P256K1 ([secp256k1](#)), commonly used for cryptocurrencies.

The ECC key spec that you choose might be determined by your security standards or the requirements of your task. In general, use the curve with the most points that is practical and affordable for your task.

If you're creating an asymmetric CMK to use with cryptocurrencies, use the ECC\_SECG\_P256K1 key spec. You can also use this key spec for other purposes, but it is required for Bitcoin, and other cryptocurrencies.

CMKs with different ECC key specs are priced differently and are subject to different request quotas. For information about AWS KMS pricing, see [AWS Key Management Service Pricing](#). For information about request quotas, see [Request Quotas \(p. 355\)](#).

The following table shows the signing algorithms that AWS KMS supports for each of the ECC key specs. You cannot configure a CMK to use particular signing algorithms. However, you can use the [kms:SigningAlgorithm \(p. 109\)](#) policy condition to specify the signing algorithms that principals are allowed to use with the CMK.

#### Supported signing algorithms for ECC key specs

Key spec	Signing algorithm	Algorithm description
ECC_NIST_P256	ECDSA_SHA_256	NIST FIPS 186-4, Section 6.4, ECDSA signature using the curve specified by the key and SHA-256 for the message digest.
ECC_NIST_P384	ECDSA_SHA_384	NIST FIPS 186-4, Section 6.4, ECDSA signature using the curve specified by the key and SHA-384 for the message digest.
ECC_NIST_P521	ECDSA_SHA_512	NIST FIPS 186-4, Section 6.4, ECDSA signature using the curve specified by the key and SHA-512 for the message digest.
ECC_SECG_P256K1	ECDSA_SHA_256	NIST FIPS 186-4, Section 6.4, ECDSA signature using the curve specified by the key and SHA-256 for the message digest.

## Viewing the Cryptographic Configuration of CMKs

After you create your CMK, you can view its cryptographic configuration. You cannot change the configuration of a CMK after it is created. If you prefer a different configuration, delete the CMK and create it again.

You can find the cryptographic configuration of your CMKs, include the key spec, key usage, and supported encryption or signing algorithms, in the AWS KMS console or by using the AWS KMS API. For details, see [Viewing Keys \(p. 22\)](#).

In the AWS KMS console, the details page for each CMK includes a **Cryptographic Configuration** section that displays cryptographic details about your CMKs. For example, the following image shows the Cryptographic Configuration section for an RSA CMK used for signing and verification.

▼ Cryptographic configuration		
Key Type Asymmetric	Key Spec ⓘ RSA_2048	Signing algorithms RSASSA_PKCS1_V1_5_SHA_256 RSASSA_PKCS1_V1_5_SHA_384 RSASSA_PKCS1_V1_5_SHA_512 RSASSA_PSS_SHA_256 RSASSA_PSS_SHA_384 RSASSA_PSS_SHA_512
Origin AWS_KMS	Key Usage Sign and verify	

In the AWS KMS API, use the [DescribeKey](#) operation. The `KeyMetadata` structure in the response includes the cryptographic configuration of the CMK. For example, `DescribeKey` returns the following response for an RSA CMK used for signing and verification.

```
{
  "KeyMetadata": {
    "AWSAccountId": "111122223333",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "CreationDate": 1571767572.317,
    "Enabled": false,
    "Description": "",
    "KeyUsage": "SIGN_VERIFY",
    "KeyState": "Disabled",
    "Origin": "AWS_KMS",
    "KeyManager": "CUSTOMER",
    "CustomerMasterKeySpec": "RSA_2048",
    "SigningAlgorithms": [
      "RSASSA_PKCS1_V1_5_SHA_256",
      "RSASSA_PKCS1_V1_5_SHA_384",
      "RSASSA_PKCS1_V1_5_SHA_512",
      "RSASSA_PSS_SHA_256",
      "RSASSA_PSS_SHA_384",
      "RSASSA_PSS_SHA_512"
    ]
  }
}
```

## Comparing Symmetric and Asymmetric CMKs

You can create and manage symmetric and asymmetric CMKs by using the AWS KMS console and the AWS KMS API. However, AWS KMS supports different features for CMKs of different types.

For example, you can only use symmetric CMKs to [generate symmetric data keys](#) and [asymmetric data key pairs](#). Also, [importing key material \(p. 147\)](#) and [automatic key rotation \(p. 142\)](#) are supported only for symmetric CMKs, and you can create only symmetric CMKs in a [custom key store \(p. 172\)](#).

The following table lists the AWS KMS operations that you can use to create and manage CMKs of each type. If you use the operation on a CMK that doesn't support it, the operation fails.

**Note**

**AWS KMS Operations With Symmetric and Asymmetric CMKs**

AWS KMS API Operation	Symmetric CMKs	Asymmetric CMKs (ENCRYPT_DECRYPT)	Asymmetric CMKs (SIGN_VERIFY)

# Rotating Customer Master Keys

Cryptographic best practices discourage extensive reuse of encryption keys. To create new cryptographic material for your AWS Key Management Service (AWS KMS) customer master keys (CMKs), you can create new CMKs, and then change your applications or aliases to use the new CMKs. Or, you can enable automatic key rotation for an existing CMK.

When you enable *automatic key rotation* for a CMK, AWS KMS generates new cryptographic material for the CMK every year. AWS KMS also saves the CMK's older cryptographic material in perpetuity so it can be used to decrypt data that it encrypted. AWS KMS does not delete any rotated key material until you [delete the CMK \(p. 160\)](#).

Key rotation changes only the CMK's *backing key*, which is the cryptographic material that is used in encryption operations. The CMK is the same logical resource, regardless of whether or how many times its backing key changes. The properties of the CMK do not change, as shown in the following image.

Automatic key rotation has the following benefits:

- The properties of the CMK, including its key ID, key ARN, region, policies, and permissions, do not change when the key is rotated.
- You do not need to change applications or aliases that refer to the CMK ID or ARN.
- After you enable key rotation, AWS KMS rotates the CMK automatically every year. You don't need to remember or schedule the update.

However, automatic key rotation has no effect on the data that the CMK protects. It does not rotate the data keys that the CMK generated or re-encrypt any data protected by the CMK, and it will not mitigate the effect of a compromised data key.

You might decide to create a new CMK and use it in place of the original CMK. This has the same effect as rotating the key material in an existing CMK, so it's often thought of as [manually rotating the key \(p. 145\)](#). Manual rotation is a good choice when you want to control the key rotation schedule. It also provides a way to rotate CMKs that are not eligible for automatic key rotation, including [asymmetric CMKs \(p. 129\)](#), CMKs in [custom key stores \(p. 172\)](#), and CMKs with [imported key material \(p. 142\)](#).

## More Information About Key Rotation

Rotating customer managed CMKs might result in extra monthly charges. For details, see [AWS Key Management Service Pricing](#). For more detailed information about backing keys and rotation, see the [KMS Cryptographic Details](#) whitepaper.

#### Topics

- [How Automatic Key Rotation Works \(p. 143\)](#)
- [How to Enable and Disable Automatic Key Rotation \(p. 144\)](#)
- [Rotating Keys Manually \(p. 145\)](#)

## How Automatic Key Rotation Works

Key rotation in AWS KMS is a cryptographic best practice that is designed to be transparent and easy to use.

- **Backing key management.** AWS KMS retains all backing keys for a CMK, even if key rotation is disabled. The backing keys are deleted only when the CMK is deleted. When you use a CMK to encrypt, AWS KMS uses the current backing key. When you use the CMK to decrypt, AWS KMS uses the backing key that was used to encrypt.
- **Enable and disable key rotation.** Automatic key rotation is disabled by default on customer managed CMKs. When you enable (or re-enable) key rotation, AWS KMS automatically rotates the CMK 365 days after the enable date and every 365 days thereafter.
- **Disabled CMKs.** While a CMK is disabled, AWS KMS does not rotate it. However, the key rotation status does not change, and you cannot change it while the CMK is disabled. When the CMK is re-enabled, if the backing key is more than 365 days old, AWS KMS rotates it immediately and every 365 days thereafter. If the backing key is less than 365 days old, AWS KMS resumes the original key rotation schedule.
- **CMKs pending deletion.** While a CMK is pending deletion, AWS KMS does not rotate it. The key rotation status is set to `false` and you cannot change it while deletion is pending. If deletion is canceled, the previous key rotation status is restored. If the backing key is more than 365 days old, AWS KMS rotates it immediately and every 365 days thereafter. If the backing key is less than 365 days old, AWS KMS resumes the original key rotation schedule.
- **AWS managed CMKs.** You cannot manage key rotation for [AWS managed CMKs \(p. 4\)](#). AWS KMS automatically rotates AWS managed CMKs every three years (1095 days).
- **Monitoring key rotation.** When AWS KMS automatically rotates the key material for an [AWS managed CMK \(p. 4\)](#) or [customer managed CMK \(p. 3\)](#), it writes the **KMS CMK Rotation** event to [Amazon CloudWatch Events](#). You can use this event to verify that the CMK was rotated.
- **Unsupported CMK types.** Automatic key rotation is *not* supported on the following types of CMKs, but you can [rotate these CMKs manually \(p. 145\)](#).
  - [Asymmetric CMKs \(p. 130\)](#)
  - CMKs in [custom key stores \(p. 172\)](#)
  - CMKs that have [imported key material \(p. 147\)](#)

# How to Enable and Disable Automatic Key Rotation

You can use the AWS KMS console or the AWS KMS API to enable and disable automatic key rotation, and view the rotation status of any customer managed CMK.

When you enable automatic key rotation, AWS KMS rotates the CMK 365 days after the enable date and every 365 days thereafter.

## Topics

- [Enabling and Disabling Key Rotation \(Console\) \(p. 144\)](#)
- [Enabling and Disabling Key Rotation \(KMS API\) \(p. 144\)](#)

## Enabling and Disabling Key Rotation (Console)

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**. (You cannot enable or disable rotation of AWS managed keys. They are automatically rotated every three years.)
4. Choose the alias or key ID of a CMK.
5. Choose the **Key rotation** tab.

The **Key rotation** tab only appears on the detail page of symmetric CMKs with key material that AWS KMS generated (the **Origin** is **AWS\_KMS**). You cannot automatically rotate asymmetric CMKs, CMKs with [imported key material \(p. 147\)](#), or CMKs in [custom key stores \(p. 172\)](#). However, you can [rotate them manually \(p. 145\)](#).

6. Select or clear the **Automatically rotate this CMK every year** check box.

### Note

If a CMK is disabled or pending deletion, the **Automatically rotate this CMK every year** check box is cleared, and you cannot change it. The key rotation status is restored when you enable the CMK or cancel deletion. For details, see [How Automatic Key Rotation Works \(p. 143\)](#) and [How Key State Affects Use of a Customer Master Key \(p. 223\)](#).

7. Choose **Save**.

## Enabling and Disabling Key Rotation (KMS API)

You can use the [AWS Key Management Service \(AWS KMS\) API](#) to enable and disable automatic key rotation, and view the current rotation status of any customer managed CMK. These examples use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

The [EnableKeyRotation](#) operation enables automatic key rotation for the specified CMK. The [DisableKeyRotation](#) operation disables it. To identify the CMK, use its key ID, key ARN, alias name, or alias ARN. By default, key rotation is disabled for customer managed CMKs.

The following example enables key rotation on the specified symmetric CMK and uses the [GetKeyRotationStatus](#) operation to see the result. Then, it disables key rotation and, again, uses [GetKeyRotationStatus](#) to see the change.

```
$ aws kms enable-key-rotation --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

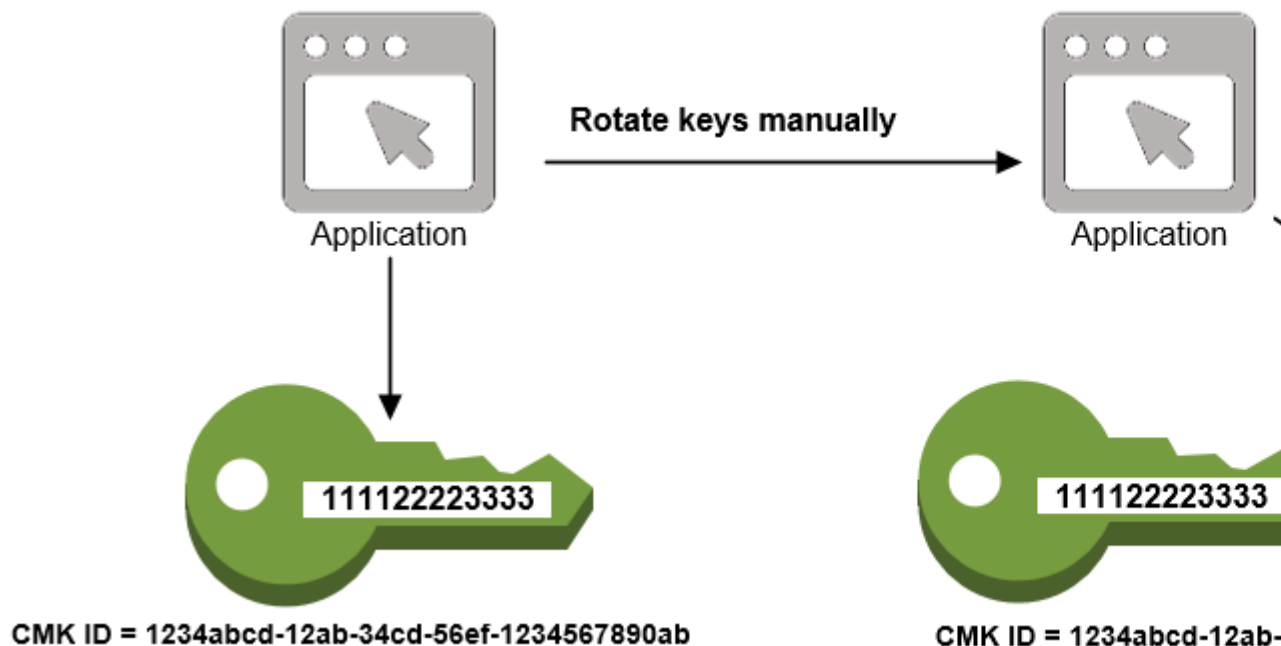

```
$ aws kms get-key-rotation-status --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
{
  "KeyRotationEnabled": true
}

$ aws kms disable-key-rotation --key-id 1234abcd-12ab-34cd-56ef-1234567890ab

$ aws kms get-key-rotation-status --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
{
  "KeyRotationEnabled": false
}
```

## Rotating Keys Manually

You might want to create a new CMK and use it in place of a current CMK instead of enabling automatic key rotation. When the new CMK has different cryptographic material than the current CMK, using the new CMK has the same effect as changing the backing key in an existing CMK. The process of replacing one CMK with another is known as *manual key rotation*.

You might prefer to rotate keys manually so you can control the rotation frequency. It's also a good solution for CMKs that are not eligible for automatic key rotation, such as asymmetric CMKs, CMKs in [custom key stores](#) (p. 172) and CMKs with [imported key material](#) (p. 147).

### Note

When you begin using the new CMK, be sure to keep the original CMK enabled so that AWS KMS can decrypt data that the original CMK encrypted. When decrypting data, KMS identifies the CMK that was used to encrypt the data, and it uses the same CMK to decrypt the data. As long as you keep both the original and new CMKs enabled, AWS KMS can decrypt any data that was encrypted by either CMK.

Because the new CMK is a different resource from the current CMK, it has a different key ID and ARN. When you change CMKs, you need to update references to the CMK ID or ARN in your applications.

Aliases, which associate a friendly name with a CMK, make this process easier. Use an alias to refer to a CMK in your applications. Then, when you want to change the CMK that the application uses, change the target CMK of the alias.

To update the target CMK of an alias, use [UpdateAlias](#) operation in the AWS KMS API. For example, this command updates the `TestCMK` alias to point to a new CMK. Because the operation does not return any output, the example uses the [ListAliases](#) operation to show that the alias is now associated with a different CMK.

```
$ aws kms list-aliases
{
  "Aliases": [
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/TestCMK",
      "AliasName": "alias/TestCMK",
      "TargetKeyId": "1234abcd-12ab-34cd-56ef-1234567890ab"
    },
  ]
}

$ aws kms update-alias --alias-name alias/TestCMK --target-key-id 0987dcba-09fe-87dc-65ba-ab0987654321

$ aws kms list-aliases
{
  "Aliases": [
    {
      "AliasArn": "arn:aws:kms:us-west-2:111122223333:alias/TestCMK",
      "AliasName": "alias/TestCMK",
      "TargetKeyId": "0987dcba-09fe-87dc-65ba-ab0987654321"
    },
  ]
}
```

# Importing Key Material in AWS Key Management Service (AWS KMS)

A customer master key (CMK) is a logical representation of a master key in AWS KMS. In addition to the master key's identifiers and other metadata including its creation date, description, and [key state](#) (p. 223), a CMK contains the *key material* used to encrypt and decrypt data. When you [create a CMK](#) (p. 17), by default AWS KMS generates the key material for that CMK. But you can create a CMK without key material and then import your own key material into that CMK, a feature often known as "bring your own key" (BYOK).

Imported key material is supported only for symmetric CMKs in AWS KMS key stores. It is not supported on asymmetric CMK or CMKs in [custom key stores](#) (p. 172).

## Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

When you use imported key material, you remain responsible for the key material while allowing AWS KMS to use a copy of it. You might choose to do this for one or more of the following reasons:

- To prove that you generated the key material using a source of entropy that meets your requirements.
- To use key material from your own infrastructure with AWS services, and to use AWS KMS to manage the lifecycle of that key material within AWS.
- To set an expiration time for the key material in AWS and to [manually delete it](#) (p. 157), but to also make it available again in the future. In contrast, [scheduling key deletion](#) (p. 160) requires a waiting period of 7 to 30 days, after which you cannot recover the deleted CMK.
- To own the original copy of the key material, and to keep it outside of AWS for additional durability and disaster recovery during the complete lifecycle of the key material.

For information about important differences between CMKs with imported key material and those with key material generated by AWS KMS, see [About Imported Key Material](#) (p. 147).

The key material you import must be a 256-bit symmetric encryption key.

## Topics

- [About Imported Key Material](#) (p. 147)
- [How To Import Key Material](#) (p. 148)
- [How to Reimport Key Material](#) (p. 148)
- [How to Identify CMKs with Imported Key Material](#) (p. 149)

## About Imported Key Material

Before you decide to import key material into AWS KMS, you should understand the following characteristics of imported key material.

### Secure key generation

You are responsible for generating the key material using a source of randomness that meets your security requirements.

### One key per CMK

When you import key material into a CMK, the CMK is permanently associated with that key material. You can [reimport the same key material \(p. 148\)](#), but you cannot import different key material into that CMK. Also, you cannot [enable automatic key rotation \(p. 142\)](#) for a CMK with imported key material. However, you can [manually rotate a CMK \(p. 145\)](#) with imported key material.

### One CMK per ciphertext

When you encrypt data under a KMS CMK, the ciphertext cannot be decrypted with any other CMK. This is true even when you import the same key material into a different CMK.

### Availability and durability

You are responsible for the key material's overall availability and durability. AWS KMS is designed to keep imported key material highly available. But the service does not maintain the durability of imported key material at the same level as key material generated on your behalf. This difference is meaningful in the following cases:

- When you set an expiration time for your imported key material, AWS KMS deletes the key material after it expires. AWS KMS does not delete the CMK or its metadata. You cannot set an expiration time for key material generated by AWS KMS.
- When you [manually delete imported key material \(p. 157\)](#), AWS KMS deletes the key material but does not delete the CMK or its metadata. In contrast, [scheduling key deletion \(p. 160\)](#) requires a waiting period of 7 to 30 days, after which AWS KMS deletes the key material and all of the CMK's metadata.
- In the unlikely event of certain regionwide failures that affect the service (such as a total loss of power), AWS KMS cannot automatically restore your imported key material. However, AWS KMS can restore the CMK and its metadata.

To restore the key material after events like these, you must retain a copy of the key material in a system that you control. Then, you can reimport it into the CMK.

## How To Import Key Material

The following overview explains how to import your key material into AWS KMS. For more details about each step in the process, see the corresponding topic.

1. [Create a symmetric CMK with no key material \(p. 150\)](#) – To get started with importing key material, first create a symmetric CMK whose *origin* is `EXTERNAL`. This indicates that the key material was generated outside of AWS KMS and prevents AWS KMS from generating key material for the CMK. In a later step you will import your own key material into this CMK.
2. [Download the public key and import token \(p. 152\)](#) – After completing step 1, download a public key and an import token. These items protect the import of your key material to AWS KMS.
3. [Encrypt the key material \(p. 155\)](#) – Use the public key that you downloaded in step 2 to encrypt the key material that you created on your own system.
4. [Import the key material \(p. 156\)](#) – Upload the encrypted key material that you created in step 3 and the import token that you downloaded in step 2.

## How to Reimport Key Material

If you manage a CMK with imported key material, you might need to reimport the key material, either because the key material expired, or because the key material was accidentally deleted or lost.

You must reimport the same key material that was originally imported into the CMK. You cannot import different key material into a CMK. Also, AWS KMS cannot create key material for a CMK that is created without key material.

To reimport key material, use the same procedure that you used to [import the key material \(p. 148\)](#) the first time, with the following exceptions.

- Use an existing CMK, instead of creating a new CMK. You can skip [Step 1 \(p. 150\)](#) of the import procedure.
- If the CMK contains key material, you must [delete the existing key material \(p. 157\)](#) before you reimport the key material.

Each time you import key material to a CMK, you need to [download and use a new wrapping key and import token \(p. 152\)](#) for the CMK. The wrapping procedure does not affect the content of the key material, so you can use different wrapping keys (and different import tokens) to import the same key material.

## How to Identify CMKs with Imported Key Material

When you create a CMK with no key material, the value of the `Origin` property of the CMK is `EXTERNAL`, and it cannot be changed. You cannot convert a key that is designed to use imported key material to one that uses the key material that AWS KMS provides.

You can identify CMKs that require imported key material in the AWS KMS console or by using the AWS KMS API.

### To identify the value of the `Origin` property of CMKs (Console)

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. Use either of the following techniques to view the `Origin` property of your CMKs.
  - To add an **Origin** column to your CMK table, in the upper right corner, choose the **Settings** icon. Choose **Origin** and choose **Confirm**. The **Origin** column makes it easy to identify CMKs with an `EXTERNAL` origin property value.
  - To find the value of the `Origin` property of a particular CMK, choose the key ID or alias of the CMK. The `Origin` property value appears in the **General configuration** section.

### To identify the value of the `Origin` property of CMKs (KMS API)

Use the [DescribeKey](#) operation. The response includes the `Origin` property of the CMK, as shown in the following example.

```
$ aws kms describe-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
{
  "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
  "Origin": "EXTERNAL",
  "KeyManager": "CUSTOMER",
```

```
"ValidTo": 1549224000.0,  
"Enabled": true,  
"AWSAccountId": "111122223333",  
"Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",  
"CreationDate": 1517867689.949,  
"KeyUsage": "ENCRYPT_DECRYPT",  
"Description": "example-key",  
"KeyState": "Enabled",  
"ExpirationModel": "KEY_MATERIAL_EXPIRES"  
}
```

## Importing Key Material Step 1: Create an AWS KMS Customer Master Key (CMK) With No Key Material

By default, AWS KMS creates key material for you when you create a customer master key (CMK). To instead import your own key material, start by creating a CMK with no key material. You distinguish between these two types of CMKs by the CMK's *origin*. When AWS KMS creates the key material for you, the CMK's origin is `AWS_KMS`. When you create a CMK with no key material, the CMK's origin is `EXTERNAL`, which indicates that the key material was generated outside of AWS KMS.

A CMK with no key material is in the *pending import* state and is not available for use. To use it, you must import key material as explained later. When you import key material, the CMK's key state changes to *enabled*. For more information about key state, see [How Key State Affects Use of a Customer Master Key](#) (p. 223).

To create a CMK with no key material, you can use the AWS Management Console or the AWS KMS API. You can use the API directly by making HTTP requests, or through one of the [AWS SDKs](#) or [command line tools](#).

### Topics

- [Creating a CMK with No Key Material \(Console\)](#) (p. 150)
- [Creating a CMK with No Key Material \(KMS API\)](#) (p. 151)

## Creating a CMK with No Key Material (Console)

You can use the AWS Management Console to create a CMK with no key material. Before you do this, you can configure the console to show the **Origin** column in the list of CMKs. Imported keys have an **Origin** value of **External**.

You need to create a CMK for the imported key material only once. To reimport the same key material into an existing CMK, see [Step 2: Download the Public Key and Import Token](#) (p. 152).

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose **Create key**.
5. Choose **Symmetric**. You cannot import key material into an asymmetric CMK.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

6. Expand **Advanced options**.
7. For **Key material origin**, choose **External**.

Then select the check box next to **I understand the security, availability, and durability implications of using an imported key** to indicate that you understand the implications of using imported key material. To read about these implications, see [About Imported Key Material \(p. 147\)](#).

Choose **Next**.

8. Type an alias and (optionally) a description for the CMK.

Choose **Next**.

9. (Optional). On the **Add tags** page, add tags that identify or categorize your CMK.

Choose **Next**.

10. In the **Key administrators** section, select the IAM users and roles who can manage the CMK. For more information, see [Allows Key Administrators to Administer the CMK \(p. 52\)](#).

**Note**

IAM policies can give other IAM users and roles permission to manage the CMK.

11. (Optional) To prevent the selected IAM users and roles from deleting this CMK, in the **Key deletion** section at the bottom of the page, clear the **Allow key administrators to delete this key** check box.

Choose **Next**.

12. In the **This account** section, select the IAM users and roles in this AWS account who can use the CMK in cryptographic operations. For more information, see [Allows Key Users to Use the CMK \(p. 54\)](#).

**Note**

IAM policies can give other IAM users and roles permission to use the CMK.

13. (Optional) You can allow other AWS accounts to use this CMK for cryptographic operations. To do so, in the **Other AWS accounts** section at the bottom of the page, choose **Add another AWS account** and enter the AWS account identification number of an external account. To add multiple external accounts, repeat this step.

**Note**

To allow principals in the external accounts to use the CMK, Administrators of the external account must create IAM policies that provide these permissions. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

Choose **Next**.

14. On the **Review and edit key policy** page, review and edit the policy document for the new CMK. When you're done, choose **Finish**.

If the operation succeeds, you have created a CMK with no key material. Its status is **Pending import**. To continue the process now, see [Downloading the Public Key and Import Token \(Console\) \(p. 153\)](#). To continue the process later, choose **Cancel**.

Next: [Step 2: Download the Public Key and Import Token \(p. 152\)](#).

## Creating a CMK with No Key Material (KMS API)

To use the [AWS KMS API](#) to create a symmetric CMK with no key material, send a [CreateKey](#) request with the `Origin` parameter set to `EXTERNAL`. The following example shows how to do this with the [AWS Command Line Interface \(AWS CLI\)](#).

```
$ aws kms create-key --origin EXTERNAL
```

When the command is successful, you see output similar to the following. The CMK's Origin is `EXTERNAL` and its `KeyState` is `PendingImport`.

```
{
  "KeyMetadata": {
    "Origin": "EXTERNAL",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Description": "",
    "Enabled": false,
    "KeyUsage": "ENCRYPT_DECRYPT",
    "KeyState": "PendingImport",
    "CreationDate": 1532127239.034,
    "Arn": "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "AWSAccountId": "111122223333"
    "KeyManager": "CUSTOMER",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

Copy the CMK's key ID from your command output to use in later steps, and then proceed to [Step 2: Download the Public Key and Import Token](#) (p. 152).

## Importing Key Material Step 2: Download the Public Key and Import Token

After you [create a symmetric customer master key \(CMK\) with no key material](#) (p. 150), you download a public key and an import token for that CMK. You need these items to import your key material. You can download both items in one step by using the AWS Management Console or the AWS KMS API.

You also download these items when you want to reimport key material into a CMK. You might do this to [manually rotate the key material](#) (p. 145), to change the expiration time for the key material, or to restore a CMK after the key material has expired or been deleted.

### Use of the Public Key

When you import key material, you don't upload the raw key material to AWS KMS. You must first encrypt the key material with the public key that you download in this step and then upload the encrypted key material to AWS KMS. When AWS KMS receives your encrypted key material, it uses the corresponding private key to decrypt it. The public key that you receive from AWS KMS is a 2048-bit RSA public key and is always unique to your AWS account.

### Use of the Import Token

The import token contains metadata to ensure that your key material is imported correctly. When you upload your encrypted key material to AWS KMS, you must upload the same import token that you download in this step.

### Select a Wrapping Algorithm

To protect your key material during import, you encrypt it using a wrapping key and wrapping algorithm. Typically, you choose an algorithm that is supported by the hardware security module (HSM) or key management system that protects your key material. You must use the RSA PKCS #1 encryption scheme with one of three padding options, represented by the following choices. These choices are listed in order of AWS preference. The technical details of the schemes represented by these choices are explained in section 7 of the [PKCS #1 Version 2.1](#) standard.

- **RSAES\_OAEP\_SHA\_256** – The RSA encryption algorithm with Optimal Asymmetric Encryption Padding (OAEP) with the SHA-256 hash function.
- **RSAES\_OAEP\_SHA\_1** – The RSA encryption algorithm with Optimal Asymmetric Encryption Padding (OAEP) with the SHA-1 hash function.
- **RSAES\_PKCS1\_V1\_5** – The RSA encryption algorithm with the padding format defined in PKCS #1 Version 1.5.

**Note**

If you plan to try the [Encrypt Key Material with OpenSSL \(p. 155\)](#) proof-of-concept example in [Step 3 \(p. 155\)](#), use **RSAES\_OAEP\_SHA\_1**.

If your HSM or key management system supports it, we recommend using **RSAES\_OAEP\_SHA\_256** to encrypt your key material. If that option is not available, you should use **RSAES\_OAEP\_SHA\_1**. If neither of the OAEP options are available, you must use **RSAES\_PKCS1\_V1\_5**. For information about how to encrypt your key material, see the documentation for the hardware security module or key management system that protects your key material.

The public key and import token are valid for 24 hours. If you don't use them to import key material within 24 hours of downloading them, you must download new ones.

To download the public key and import token, you can use the AWS Management Console or the AWS KMS API. You can use the API directly by making HTTP requests, or through one of the [AWS SDKs](#) or [command line tools](#).

**Topics**

- [Downloading the Public Key and Import Token \(Console\) \(p. 153\)](#)
- [Downloading the Public Key and Import Token \(KMS API\) \(p. 154\)](#)

## Downloading the Public Key and Import Token (Console)

You can use the AWS Management Console to download the public key and import token.

1. If you just completed the steps to [create a CMK with no key material \(p. 150\)](#) and you are on the **Download wrapping key and import token** page, skip to [Step 8](#).
2. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the navigation pane, choose **Customer managed keys**.

**Tip**

You can import key material only into a symmetric CMK with an **Origin** of **EXTERNAL**. This indicates that the CMK was created with no key material. To add the **Origin** column to

your table, in the upper-right corner of the page, choose the settings icon (  ). Turn on **Origin**, and then choose **Confirm**.

5. Choose the alias or key ID of the CMK that is pending import.
6. Expand the **Cryptographic configuration** section and view its values.

You can only import key material into CMKs with a **Key type** of **Symmetric** and an **Origin** of **EXTERNAL**. For information about creating CMKs with imported key material, see, [Importing Key Material in AWS Key Management Service \(AWS KMS\) \(p. 147\)](#).

7. Expand the **Key material** section, and then choose **Download wrapping key and import token**.

The **Key material** section appears only for symmetric CMKs that have an **Origin** value of **EXTERNAL**.

8. For **Select wrapping algorithm**, choose the option that you will use to encrypt your key material. For more information about the options, see [Select a Wrapping Algorithm \(p. 152\)](#).

If you plan to try the [Encrypt Key Material with OpenSSL \(p. 155\)](#) proof-of-concept example in [Step 3 \(p. 155\)](#), choose `RSAES_OAEP_SHA_1`.

9. Choose **Download wrapping key and import token**, and then save the file.

If you have a **Next** option, to continue the process now, choose **Next**. To continue later, choose **Cancel**. Otherwise, to close the window, choose **Cancel** or click the **X**.

10. Decompress the `.zip` file that you saved in the previous step (`ImportParameters.zip`).

The folder contains the following files:

- The wrapping key (public key), in a file named `wrappingKey_CMK_key_ID_timestamp` (for example, `wrappingKey_f44c4e20-f83c-48f4-adc6-a1ef38829760_0809092909`). This is a 2048-bit RSA public key.
  - The import token, in a file named `importToken_CMK_key_ID_timestamp` (for example, `importToken_f44c4e20-f83c-48f4-adc6-a1ef38829760_0809092909`).
  - A text file named `README_CMK_key_ID_timestamp.txt` (for example, `README_f44c4e20-f83c-48f4-adc6-a1ef38829760_0809092909.txt`). This file contains information about the wrapping key (public key), the wrapping algorithm to use to encrypt your key material, and the date and time when the wrapping key (public key) and import token expire.
11. To continue the process, see [encrypt your key material \(p. 155\)](#).

## Downloading the Public Key and Import Token (KMS API)

To use the [AWS KMS API](#) to download the public key and import token, send a [GetParametersForImport](#) request that specifies the CMK for which you are downloading these items. The following example shows how to do this with the [AWS CLI](#).

This example specifies `RSAES_OAEP_SHA_1` as the encryption option. To specify a different option, replace `RSAES_OAEP_SHA_1` with `RSAES_OAEP_SHA_256` or `RSAES_PKCS1_V1_5`. Replace `1234abcd-12ab-34cd-56ef-1234567890ab` with the key ID of the CMK for which to download the public key and import token. You can use the CMK's key ID or Amazon Resource Name (ARN), but you cannot use an alias for this operation.

### Note

If you plan to try the [Encrypt Key Material with OpenSSL \(p. 155\)](#) proof-of-concept example in [Step 3 \(p. 155\)](#), specify `RSAES_OAEP_SHA_1`.

```
$ aws kms get-parameters-for-import --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
                                     --wrapping-algorithm RSAES_OAEP_SHA_1 \
                                     --wrapping-key-spec RSA_2048
```

When the command is successful, you see output similar to the following:

```
{
  "ParametersValidTo": 1470933314.949,
  "PublicKey": "public key base64 encoded data",
  "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "ImportToken": "import token base64 encoded data"
}
```

When you receive this output, save the base64 encoded public key and import token in separate files. Then base64 decode each file into binary data and save the binary data in new files. Doing so prepares these items for later steps. See the following example.

#### To prepare the public key and import token for later steps

1. Copy the public key's base64 encoded data (represented by *public key base64 encoded data* in the example output), paste it into a new file, and then save the file. Give the file a descriptive name, for example `PublicKey.b64`.
2. Use [OpenSSL](#) to base64 decode the file's contents and save the decoded data to a new file. The following example decodes the data in the file that you saved in the previous step (`PublicKey.b64`) and saves the output to a new file named `PublicKey.bin`.

```
$ openssl enc -d -base64 -A -in PublicKey.b64 -out PublicKey.bin
```

Repeat these two steps for the import token, and then proceed to [Step 3: Encrypt the Key Material](#) (p. 155).

## Importing Key Material Step 3: Encrypt the Key Material

After you [download the public key and import token](#) (p. 152), you use the public key to encrypt your key material. The key material must be in binary format.

Typically, you encrypt your key material when you export it from your hardware security module (HSM) or key management system. For information about how to export key material in binary format, see the documentation for your HSM or key management system. You can also refer to the following section that provides a proof of concept demonstration using OpenSSL.

When you encrypt your key material, use the encryption scheme with the padding option that you specified when you [downloaded the public key and import token](#) (p. 152) (RSAES\_OAEP\_SHA\_256, RSAES\_OAEP\_SHA\_1, or RSAES\_PKCS1\_V1\_5).

### Example: Encrypt Key Material with OpenSSL

The following example demonstrates how to use [OpenSSL](#) to generate a 256-bit symmetric key and then encrypt this key material for import into a KMS customer master key (CMK).

#### Important

This example is a proof of concept demonstration only. For production systems, use a more secure method (such as a commercial HSM or key management system) to generate and store your key material.

The `RSAES_OAEP_SHA_1` encryption algorithm works best with this example. Before running the example, make sure that you used `RSAES_OAEP_SHA_1` for the wrapping algorithm in [Step 2](#) (p. 152). If necessary, repeat the step to download and import the public key and token.

#### To use OpenSSL to generate binary key material and encrypt it for import into AWS KMS

1. Use the following command to generate a 256-bit symmetric key and save it in a file named `PlaintextKeyMaterial.bin`.

```
$ openssl rand -out PlaintextKeyMaterial.bin 32
```

2. Use the following command to encrypt the key material with the public key that you downloaded previously (see [Downloading the Public Key and Import Token \(KMS API\)](#) (p. 154)) and save it in a file named `EncryptedKeyMaterial.bin`. Replace `PublicKey.bin` with the name of the file that contains the public key. If you downloaded the public key from the console, this file is named `wrappingKey_CMK_key_ID_timestamp` (for example, `wrappingKey_f44c4e20-f83c-48f4-adc6-a1ef38829760_0809092909`).

```
$ openssl rsautl -encrypt \  
    -in PlaintextKeyMaterial.bin \  
    -oaep \  
    -inkey PublicKey.bin \  
    -keyform DER \  
    -pubin \  
    -out EncryptedKeyMaterial.bin
```

Proceed to [Step 4: Import the Key Material](#) (p. 156).

## Importing Key Material Step 4: Import the Key Material

After you [encrypt your key material](#) (p. 155), you can import the key material to use with an AWS KMS customer master key (CMK). To import key material, you upload the encrypted key material from [Step 3: Encrypt the Key Material](#) (p. 155) and the import token that you downloaded at [Step 2: Download the Public Key and Import Token](#) (p. 152). You must import key material into the same CMK that you specified when you downloaded the public key and import token.

When you import key material, you can optionally specify a time at which the key material expires. When the key material expires, AWS KMS deletes the key material and the CMK becomes unusable. To use the CMK again, you must reimport key material.

After you successfully import key material, the CMK's key state changes to enabled, and you can use the CMK.

To import key material, you can use the AWS Management Console or the AWS KMS API. You can use the API directly by making HTTP requests, or through one of the [AWS SDKs](#) or [command line tools](#).

### Topics

- [Import Key Material \(Console\)](#) (p. 156)
- [Import Key Material \(KMS API\)](#) (p. 157)

## Import Key Material (Console)

You can use the AWS Management Console to import key material.

1. If you are on the **Download wrapping key and import token** page, skip to [Step 8](#).
2. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
3. To change the AWS Region, use the Region selector in the upper-right corner of the page.
4. In the navigation pane, choose **Customer managed keys**.
5. Choose the key ID or alias of the CMK for which you downloaded the public key and import token.
6. Expand the **Cryptographic configuration** section and view its values.

You can only import key material into CMKs with a **Key type** of **Symmetric** and an **Origin** of **EXTERNAL**. For information about creating CMKs with imported key material, see [Importing Key Material in AWS Key Management Service \(AWS KMS\)](#) (p. 147).

- Expand the **Key material** section and then choose **Upload key material**.

The **Key material** section appears only for CMKs with a **Key type** of **Symmetric** and an **Origin** value of **EXTERNAL**.

- In the **Encrypted key material and import token** section, under **Wrapped key material**, choose **Choose file**. Then upload the file that contains your wrapped (encrypted) key material.
- In the **Encrypted key material and import token** section, under **Import token**, choose **Choose file**. Upload the file that contains the import token that you [downloaded](#) (p. 153).
- In the **Expiration option** section, you determine whether the key material expires. To set an expiration date and time, choose **Key material expires**, and use the calendar to select a date and time.
- Choose **Finish** or **Upload key material**.

## Import Key Material (KMS API)

To use the [AWS KMS API](#) to import key material, send an `ImportKeyMaterial` request. The following example shows how to do this with the [AWS CLI](#).

This example specifies an expiration time for the key material. To import key material with no expiration, replace `KEY_MATERIAL_EXPIRES` with `KEY_MATERIAL_DOES_NOT_EXPIRE` and omit the `--valid-to` parameter.

To use this example:

- Replace `1234abcd-12ab-34cd-56ef-1234567890ab` with the key ID of the CMK that you used when you downloaded the public key and import token. To identify the CMK, use its key ID or ARN. You cannot use an alias for this operation.
- Replace `EncryptedKeyMaterial.bin` with the name of the file that contains the encrypted key material.
- Replace `ImportToken.bin` with the name of the file that contains the import token.

```
$ aws kms import-key-material --key-id 1234abcd-12ab-34cd-56ef-1234567890ab \
    --encrypted-key-material fileb://EncryptedKeyMaterial.bin \
    --import-token fileb://ImportToken.bin \
    --expiration-model KEY_MATERIAL_EXPIRES \
    --valid-to 2016-11-08T12:00:00-08:00
```

## Deleting Imported Key Material

When you import key material, you can specify an expiration date. When the key material expires, AWS KMS deletes the key material and the customer master key (CMK) becomes unusable. You can also delete key material on demand. Whether you wait for the key material to expire or you delete it manually, the effect is the same. AWS KMS deletes the key material, the CMK's [key state](#) (p. 223) changes to *pending import*, and the CMK is unusable. To use the CMK again, you must reimport the same key material.

Deleting key material affects the CMK immediately, but you can reverse the deletion of key material by reimporting the same key material into the CMK. In contrast, deleting a CMK is irreversible. If you

[schedule key deletion \(p. 160\)](#) and the required waiting period expires, AWS KMS deletes the key material and all metadata associated with the CMK.

To delete key material, you can use the AWS Management Console or the AWS KMS API. You can use the API directly by making HTTP requests, or through one of the [AWS SDKs](#) or [command line tools](#).

#### Topics

- [How Deleting Key Material Affects AWS Services Integrated With AWS KMS \(p. 158\)](#)
- [Delete Key Material \(Console\) \(p. 158\)](#)
- [Delete Key Material \(KMS API\) \(p. 159\)](#)

## How Deleting Key Material Affects AWS Services Integrated With AWS KMS

When you delete key material, the CMK becomes unusable right away. However, any [data keys \(p. 4\)](#) that AWS services are using are not immediately affected. This means that deleting key material might not immediately affect all of the data and AWS resources that are protected under the CMK, though they are affected eventually.

Several AWS services integrate with AWS KMS to protect your data. Some of these services, such as [Amazon EBS](#) and [Amazon Redshift](#), use a [customer master key \(p. 2\)](#) (CMK) in AWS KMS to generate a [data key \(p. 4\)](#), and then use the data key to encrypt your data. These plaintext data keys persist in memory as long as the data they are protecting is actively in use.

For example, consider this scenario:

1. You create an encrypted EBS volume and specify a CMK with imported key material. Amazon EBS asks AWS KMS to use your CMK to [generate an encrypted data key](#) for the volume. Amazon EBS stores the encrypted data key with the volume.
2. When you attach the EBS volume to an EC2 instance, Amazon EC2 asks AWS KMS to use your CMK to decrypt the EBS volume's encrypted data key. Amazon EC2 stores the plaintext data key in hypervisor memory and uses it to encrypt disk I/O to the EBS volume. The data key persists in memory as long as the EBS volume is attached to the EC2 instance.
3. You delete the imported key material from the CMK, which makes it unusable. This has no immediate effect on the EC2 instance or the EBS volume. The reason is that Amazon EC2 is using the plaintext data key—not the CMK—to encrypt all disk I/O while the volume is attached to the instance.
4. However, when the encrypted EBS volume is detached from the EC2 instance, Amazon EBS removes the plaintext key from memory. The next time the encrypted EBS volume is attached to an EC2 instance, the attachment fails, because Amazon EBS cannot use the CMK to decrypt the volume's encrypted data key. To use the EBS volume again, you must reimport the same key material into the CMK.

## Delete Key Material (Console)

You can use the AWS Management Console to delete key material.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Do one of the following:

- Select the check box for a CMK with imported key material. Choose **Key actions, Delete key material**.
  - Choose the alias or key ID of a CMK with imported key material. In the **Key material** section of the page, choose **Delete key material**.
5. Confirm that you want to delete the key material and then choose **Delete key material**. The CMK's status, which corresponds to its [key state \(p. 223\)](#), changes to **Pending import**.

## Delete Key Material (KMS API)

To use the [AWS KMS API](#) to delete key material, send a [DeleteImportedKeyMaterial](#) request. The following example shows how to do this with the [AWS CLI](#).

Replace `1234abcd-12ab-34cd-56ef-1234567890ab` with the key ID of the CMK whose key material you want to delete. You can use the CMK's key ID or ARN but you cannot use an alias for this operation.

```
$ aws kms delete-imported-key-material --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

# Deleting Customer Master Keys

Deleting a customer master key (CMK) in AWS Key Management Service (AWS KMS) is destructive and potentially dangerous. It deletes the key material and all metadata associated with the CMK and is irreversible. After a CMK is deleted, you can no longer decrypt the data that was encrypted under that CMK, which means that data becomes unrecoverable. You should delete a CMK only when you are sure that you don't need to use it anymore. If you are not sure, consider [disabling the CMK \(p. 41\)](#) instead of deleting it. You can reenable a disabled CMK if you need to use it again later, but you cannot recover a deleted CMK.

Before deleting a CMK, you might want to know how many ciphertexts were encrypted under that CMK. AWS KMS does not store this information and does not store any of the ciphertexts. To get this information, you must determine on your own the past usage of a CMK. For some guidance that might help you do this, go to [Determining Past Usage of a Customer Master Key \(p. 169\)](#).

AWS KMS never deletes your CMKs unless you explicitly schedule them for deletion and the mandatory waiting period expires.

However, you might choose to delete a CMK for one or more of the following reasons:

- To complete the key lifecycle for CMKs that you no longer need
- To avoid the management overhead and [costs](#) associated with maintaining unused CMKs
- To reduce the number of CMKs that count against your [CMK resource quota \(p. 354\)](#)

## Note

If you [close or delete your AWS account](#), your CMKs become inaccessible and you are no longer billed for them. You do not need to schedule deletion of your CMKs separate from closing the account.

## Topics

- [How Deleting Customer Master Keys Works \(p. 160\)](#)
- [Scheduling and Canceling Key Deletion \(p. 162\)](#)
- [Adding Permission to Schedule and Cancel Key Deletion \(p. 164\)](#)
- [Creating an Amazon CloudWatch Alarm to Detect Usage of a Customer Master Key that is Pending Deletion \(p. 165\)](#)
- [Determining Past Usage of a Customer Master Key \(p. 169\)](#)

## How Deleting Customer Master Keys Works

Users who are authorized delete symmetric and asymmetric customer master keys (CMKs). The procedure is the same for both types of CMKs.

Because it is destructive and potentially dangerous to delete a CMK, AWS KMS enforces a waiting period. To delete a CMK in AWS KMS you *schedule key deletion*. You can set the waiting period from a minimum of 7 days up to a maximum of 30 days. The default waiting period is 30 days.

During the waiting period, the CMK status and key state is **Pending deletion**.

- A CMK that is pending deletion cannot be used in any cryptographic operations.
- AWS KMS does not [rotate the backing keys \(p. 143\)](#) of CMKs that are pending deletion.

After the waiting period ends, AWS KMS deletes the CMK and all AWS KMS data associated with it, including all aliases that point to it.

When you schedule key deletion, AWS KMS reports the date and time when the waiting period ends. This date and time is at least the specified number of days from when you scheduled key deletion, but it can be up to 24 hours longer. For example, suppose you schedule key deletion and specify a waiting period of 7 days. In that case, the end of the waiting period occurs no earlier than 7 days and no more than 8 days from the time of your request. You can confirm the exact date and time when the waiting period ends in the AWS Management Console, AWS CLI, or AWS KMS API.

Use the waiting period to ensure that you don't need the CMK now or in the future. You can [configure an Amazon CloudWatch alarm \(p. 165\)](#) to warn you if a person or application attempts to use the CMK during the waiting period. To recover the CMK, you can cancel key deletion before the waiting period ends. After the waiting period ends you cannot cancel key deletion, and AWS KMS deletes the CMK.

## Deleting Asymmetric CMKs

Users [who are authorized \(p. 164\)](#) can delete symmetric or asymmetric CMKs. The procedure to schedule the deletion of these CMKs is the same for both types of keys. However, because the [public key of an asymmetric CMK can be downloaded \(p. 43\)](#) and used outside of AWS KMS, the operation poses significant additional risks, especially for asymmetric CMKs used for encryption (the key usage is `ENCRYPT_DECRYPT`).

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

- When you schedule the deletion of a CMK, the key state of CMK changes to **Pending deletion**, and the CMK cannot be used in cryptographic operations. However, scheduling deletion has no effect on public keys outside of AWS KMS. Users who have the public key can continue to use them to encrypt messages. They do not receive any notification that the key state is changed. Unless the deletion is canceled, ciphertext created with the public key cannot be decrypted.
- Alarms, logs, and other strategies that detect attempted use of CMK that is pending deletion cannot detect use of the public key outside of AWS KMS.
- When the CMK is deleted, all AWS KMS actions involving that CMK fail. However, users who have the public key can continue to use them to encrypt messages. These ciphertexts cannot be decrypted.

If you must delete an asymmetric CMK with a key usage of `ENCRYPT_DECRYPT`, use your CloudTrail Log entries to determine whether the public key has been downloaded and shared. If it has, verify that the public key is not being used outside of AWS KMS. Then, consider [disabling the CMK \(p. 41\)](#) instead of deleting it.

## How Deleting Customer Master Keys Affects AWS Services Integrated With AWS KMS

Several AWS services integrate with AWS KMS to protect your data. Some of these services, such as [Amazon EBS](#) and [Amazon Redshift](#), use a [customer master key \(p. 2\)](#) (CMK) in AWS KMS to generate a [data key \(p. 4\)](#) and then use the data key to encrypt your data. These plaintext data keys persist in memory as long as the data they are protecting is actively in use.

Scheduling a CMK for deletion makes it unusable, but it does not prevent the AWS service from using data keys in memory to encrypt and decrypt your data. The service is not affected until it needs to use the CMK that is pending deletion or deleted.

For example, consider this scenario:

1. You create an encrypted EBS volume and specify a CMK. Amazon EBS asks AWS KMS to use your CMK to [generate an encrypted data key](#) for the volume. Amazon EBS stores the encrypted data key with the volume.
2. When you attach the EBS volume to an EC2 instance, Amazon EC2 asks AWS KMS to use your CMK to decrypt the EBS volume's encrypted data key. Amazon EC2 stores the plaintext data key in hypervisor memory and uses it to encrypt disk I/O to the EBS volume. The data key persists in memory as long as the EBS volume is attached to the EC2 instance.
3. You schedule the CMK for deletion, which makes it unusable. This has no immediate effect on the EC2 instance or the EBS volume, because Amazon EC2 is using the plaintext data key—not the CMK—to encrypt disk I/O to the EBS volume.

Even when the scheduled time elapses and AWS KMS deletes the CMK, there is no immediate effect on the EC2 instance or the EBS volume, because Amazon EC2 is using the plaintext data key, not the CMK.

4. However, when the encrypted EBS volume is detached from the EC2 instance, Amazon EBS removes the plaintext key from memory. The next time the encrypted EBS volume is attached to an EC2 instance, the attachment fails, because Amazon EBS cannot use the CMK to decrypt the volume's encrypted data key.

## Scheduling and Canceling Key Deletion

The following procedures describe how to schedule key deletion and cancel key deletion in AWS KMS using the AWS Management Console, the AWS CLI, and the AWS SDK for Java.

### Warning

Deleting a customer master key (CMK) in AWS KMS is destructive and potentially dangerous. You should proceed only when you are sure that you don't need to use the CMK anymore and won't need to use it in the future. If you are not sure, you should [disable the CMK \(p. 41\)](#) instead of deleting it.

Before you can delete a CMK, you must have permission to do so. If you rely on the key policy alone to specify AWS KMS permissions, you might need to add additional permissions before you can delete the CMK. For information about adding these permissions, go to [Adding Permission to Schedule and Cancel Key Deletion \(p. 164\)](#).

### Ways to schedule and cancel key deletion

- [Scheduling and Canceling Key Deletion \(Console\) \(p. 162\)](#)
- [Scheduling and Canceling Key Deletion \(AWS CLI\) \(p. 163\)](#)
- [Scheduling and Canceling Key Deletion \(AWS SDK for Java\) \(p. 163\)](#)

## Scheduling and Canceling Key Deletion (Console)

You can schedule and cancel key deletion in the AWS Management Console.

### To schedule key deletion

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Select the check box next to the CMK that you want to delete.
5. Choose **Key actions**, **Schedule key deletion**.
6. Read and consider the warning, and the information about canceling the deletion during the waiting period. If you decide to cancel the deletion, choose **Cancel**.

7. For **Waiting period (in days)**, enter a number of days between 7 and 30.
8. Select the check box next to **Confirm you want to schedule this key for deletion in *<number of days>* days..**
9. Choose **Schedule deletion**.

The CMK status changes to **Pending deletion**.

### To cancel key deletion

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Select the check box next to the CMK that you want to recover.
5. Choose **Key actions, Cancel key deletion**.

The CMK status changes from **Pending deletion** to **Disabled**. To use the CMK, you must [enable it \(p. 41\)](#).

## Scheduling and Canceling Key Deletion (AWS CLI)

Use the `aws kms schedule-key-deletion` command to schedule key deletion from the AWS CLI as shown in the following example.

```
$ aws kms schedule-key-deletion --key-id 1234abcd-12ab-34cd-56ef-1234567890ab --pending-window-in-days 10
```

When used successfully, the AWS CLI returns output like the output shown in the following example:

```
{
  "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "DeletionDate": 1442102400.0
}
```

Use the `aws kms cancel-key-deletion` command to cancel key deletion from the AWS CLI as shown in the following example.

```
$ aws kms cancel-key-deletion --key-id 1234abcd-12ab-34cd-56ef-1234567890ab
```

When used successfully, the AWS CLI returns output like the output shown in the following example:

```
{
  "KeyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
```

The status of the CMK changes from **Pending Deletion** to **Disabled**. To use the CMK, you must [enable it \(p. 41\)](#).

## Scheduling and Canceling Key Deletion (AWS SDK for Java)

The following example demonstrates how to schedule a CMK for deletion with the AWS SDK for Java. This example requires that you previously instantiated an `AWSKMSClient` as `kms`.

```
String KeyId = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
int PendingWindowInDays = 10;  
  
ScheduleKeyDeletionRequest scheduleKeyDeletionRequest =  
new  
    ScheduleKeyDeletionRequest().withKeyId(KeyId).withPendingWindowInDays(PendingWindowInDays);  
kms.scheduleKeyDeletion(scheduleKeyDeletionRequest);
```

The following example demonstrates how to cancel key deletion with the AWS SDK for Java. This example requires that you previously instantiated an `AWSKMSClient` as `kms`.

```
String KeyId = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
CancelKeyDeletionRequest cancelKeyDeletionRequest =  
new CancelKeyDeletionRequest().withKeyId(KeyId);  
kms.cancelKeyDeletion(cancelKeyDeletionRequest);
```

The status of the CMK changes from **Pending Deletion** to **Disabled**. To use the CMK, you must [enable it \(p. 41\)](#).

## Adding Permission to Schedule and Cancel Key Deletion

If you use IAM policies to allow AWS KMS permissions, all IAM users and roles that have AWS administrator access (`"Action": "*"`) or AWS KMS full access (`"Action": "kms:*"`) are already allowed to schedule and cancel key deletion for AWS KMS CMKs. If you rely on the key policy alone to allow AWS KMS permissions, you might need to add additional permissions to allow your IAM users and roles to delete CMKs. To add those permissions, see the following steps.

The following procedures describe how to add permissions to a key policy using the AWS Management Console or the AWS CLI.

### Ways to add permission to schedule and cancel key deletion

- [Adding Permission to Schedule and Cancel Key Deletion \(Console\) \(p. 164\)](#)
- [Adding Permission to Schedule and Cancel Key Deletion \(AWS CLI\) \(p. 165\)](#)

## Adding Permission to Schedule and Cancel Key Deletion (Console)

You can use the AWS Management Console to add permissions for scheduling and canceling key deletion.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose the alias or key ID of the CMK whose permissions you want to change.
5. In the **Key policy** section, under **Key deletion**, select **Allow key administrators to delete this key** and then choose **Save changes**.

### Note

If you do not see the **Allow key administrators to delete this key** option, this usually means that you have changed this key policy using the AWS KMS API. In this case, you must update the key policy document manually. Add the `kms:ScheduleKeyDeletion` and `kms:CancelKeyDeletion` permissions to the key administrators statement (`"Sid": "Allow access for Key Administrators"`) in the key policy, and then choose **Save changes**.

## Adding Permission to Schedule and Cancel Key Deletion (AWS CLI)

You can use the AWS Command Line Interface to add permissions for scheduling and canceling key deletion.

### To add permission to schedule and cancel key deletion

1. Use the `aws kms get-key-policy` command to retrieve the existing key policy, and then save the policy document to a file.
2. Open the policy document in your preferred text editor, add the `kms:ScheduleKeyDeletion` and `kms:CancelKeyDeletion` permissions to the policy statement that gives permissions to the key administrators (for example, the policy statement with `"Sid": "Allow access for Key Administrators"`). Then save the file. The following example shows a policy statement with these two permissions:

```
{
  "Sid": "Allow access for Key Administrators",
  "Effect": "Allow",
  "Principal": { "AWS": "arn:aws:iam::111122223333:user/KMSKeyAdmin" },
  "Action": [
    "kms:Create*",
    "kms:Describe*",
    "kms:Enable*",
    "kms:List*",
    "kms:Put*",
    "kms:Update*",
    "kms:Revoke*",
    "kms:Disable*",
    "kms:Get*",
    "kms>Delete*",
    "kms:ScheduleKeyDeletion",
    "kms:CancelKeyDeletion"
  ],
  "Resource": "*"
}
```

3. Use the `aws kms put-key-policy` command to apply the key policy to the CMK.

## Creating an Amazon CloudWatch Alarm to Detect Usage of a Customer Master Key that is Pending Deletion

You can combine the features of AWS CloudTrail, Amazon CloudWatch Logs, and Amazon Simple Notification Service (Amazon SNS) that notify you when someone in your account tries to use a CMK

that is pending deletion in a cryptographic operation. If you receive this notification, you might want to cancel deletion of the CMK and reconsider your decision to delete it.

The following procedures explain how to receive a notification whenever an AWS KMS API request that results in the "key ARN is pending deletion" error message is written to your CloudTrail log files. This error message indicates that a person or application tried to use the CMK in a cryptographic operation (Encrypt, Decrypt, GenerateDataKey, GenerateDataKeyWithoutPlaintext, and ReEncrypt). Because the notification is linked to the error message, it is not triggered when you use API operations that are permitted on CMKs that are pending deletion, such as ListKeys, CancelKeyDeletion, and PutKeyPolicy. To see a list of the AWS KMS API operations that return this error message, see [How Key State Affects Use of a Customer Master Key \(p. 223\)](#).

The notification email that you receive does not list the CMK or the cryptographic operation. You can find that information in [your CloudTrail log \(p. 293\)](#). Instead, the email reports that the alarm state changed from **OK** to **Alarm**. For more information about CloudWatch Alarms and state changes, see [Creating Amazon CloudWatch Alarms](#) in the *Amazon CloudWatch User Guide*.

### Warning

This Amazon CloudWatch alarm cannot detect use of the public key of an asymmetric CMK outside of AWS KMS. For details about the special risks of deleting asymmetric CMKs used for public key cryptography, including creating ciphertexts that cannot be decrypted, see [Deleting Asymmetric CMKs \(p. 161\)](#).

### Topics

- [Requirements for a CloudWatch Alarm \(p. 166\)](#)
- [Create the CloudWatch Alarm \(p. 166\)](#)

## Requirements for a CloudWatch Alarm

Before you create a CloudWatch alarm, you must create an AWS CloudTrail trail and configure CloudTrail to deliver CloudTrail log files to Amazon CloudWatch Logs.

1. [Create a CloudTrail trail](#).

CloudTrail is automatically enabled on your AWS account when you create the account. However, for an ongoing record of events in your account, including events for AWS KMS, create a trail.

2. [Configure CloudTrail to deliver your log files CloudWatch Logs](#).

Configure delivery of your CloudTrail log files to CloudWatch Logs. This allows CloudWatch Logs to monitor the logs for AWS KMS API requests that attempt to use a CMK that is pending deletion.

## Create the CloudWatch Alarm

To receive a notification when AWS KMS API requests attempt to use a CMK that is pending deletion in a cryptographic operation, create a CloudWatch alarm and configure notifications.

### To create a CloudWatch alarm that monitors attempted usage of a KMS CMK that is pending deletion

1. Sign in to the AWS Management Console and open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. Use the Region selector on the upper right to choose the AWS Region you want to monitor.
3. In the left navigation pane, choose **Logs**.

4. In the list of **Log Groups**, choose the option button next to your log group. Then choose **Create Metric Filter**.
5. For **Filter Pattern**, type or paste the following:

```
{ $.eventSource = kms* && $.errorMessage = "* is pending deletion."}
```

Choose **Assign Metric**.

6. On the **Create Metric Filter and Assign a Metric** page, do the following:
  - a. For **Metric Namespace**, type **CloudTrailLogMetrics**.
  - b. For **Metric Name**, type **KMSKeyPendingDeletionErrorCount**.
  - c. Choose **Show advanced metric settings** and for **Metric Value**, type **1**, if this is not the current value.
  - d. Choose **Create Filter**.
7. In the filter box, choose **Create Alarm**.
8. In the **Create Alarm** window, do the following:
  - a. In the **Alarm Threshold** section, for **Name**, type **KMSKeyPendingDeletionErrorAlarm**. You can also add an optional description.
  - b. Following **Whenever**, for **is**, choose **>=** and then type **1**.
  - c. For **1 out of *n* datapoints**, if necessary, type **1**.
  - d. In the **Additional settings** section, for **Treat missing data as**, choose **good (not breaching threshold)**.
  - e. In the **Actions** section, for **Send notification to**, do one of the following:
    - To use a new Amazon SNS topic, choose **New list**, and then type a new topic name, such as **KMSAlert**. For **Email list**, type at least one email address. You can type more than one email address by separating them with commas.
    - To use an existing Amazon SNS topic, choose the name of the topic to use.
  - f. Choose **Create Alarm**.

## Create Alarm

1. Select Metric
2. Define Alarm

### Alarm Threshold

Provide the details and threshold for your alarm. Use the graph on the right to help set the appropriate threshold.

Name:

Description:

Whenever: KMSKeyPendingDeletionErrorCount

is: 
for: 1 out of 1 datapoints

### Additional settings

Provide additional configuration for your alarm.

Treat missing data as:

### Actions

Define what actions are taken when your alarm changes state.

Notification

Whenever this alarm:

Send notification to: 

New list Enter list

Email list:

+ Notification
+ AutoScaling Action
+ EC2 Action

### Alarm Preview

This alarm will trigger when the blue line goes up to or above the red line for 1 datapoints within 5 minutes

Namespace: CloudTrailLogMetrics

Metric Name:

Period:

Statistic: ☒ Standard ☐ Custom

Cancel Previous Next **Create Alarm**

- If you chose to send notifications to an email address, open the email message you receive from `no-reply@sns.amazonaws.com` with a subject "AWS Notification - Subscription Confirmation." Confirm your email address by choosing the **Confirm subscription** link in the email message.

#### Note

You will not receive email notifications until after you have confirmed your email address.

After you complete this procedure, you will receive a notification each time this CloudWatch alarm enters the `ALARM` state. If you receive a notification for this alarm, it might mean that someone or something still needs to use this CMK. In that case, you should [cancel deletion of the CMK \(p. 162\)](#) to give yourself more time to determine whether you really want to delete it.

## Determining Past Usage of a Customer Master Key

Before deleting a customer master key (CMK), you might want to know how many ciphertexts were encrypted under that key. AWS KMS does not store this information, and does not store any of the ciphertexts. To obtain this information, you must determine on your own the past usage of a CMK. Knowing how a CMK was used in the past might help you decide whether or not you will need it in the future. The following guidance can help you determine the past usage of a CMK.

### Warning

These strategies for determining past and actual usage are effective only for AWS users and AWS KMS operations. They cannot detect use of the public key of an asymmetric CMK outside of AWS KMS. For details about the special risks of deleting asymmetric CMKs used for public key cryptography, including creating ciphertexts that cannot be decrypted, see [Deleting Asymmetric CMKs](#) (p. 161).

### Topics

- [Examining CMK Permissions to Determine the Scope of Potential Usage](#) (p. 169)
- [Examining AWS CloudTrail Logs to Determine Actual Usage](#) (p. 169)

## Examining CMK Permissions to Determine the Scope of Potential Usage

Determining who or what currently has access to a customer master key (CMK) might help you determine how widely the CMK was used and whether it is still needed. To learn how to determine who or what currently has access to a CMK, go to [Determining Access to an AWS KMS Customer Master Key](#) (p. 118).

## Examining AWS CloudTrail Logs to Determine Actual Usage

AWS KMS is integrated with AWS CloudTrail, so all AWS KMS API activity is recorded in CloudTrail log files. If you have CloudTrail turned on in the region where your customer master key (CMK) is located, you can examine your CloudTrail log files to view a history of all AWS KMS API activity for a particular CMK, and thus its usage history. You might be able to use a CMK's usage history to help you determine whether or not you still need it.

The following examples show CloudTrail log entries that are generated when a KMS CMK is used to protect an object stored in Amazon Simple Storage Service (Amazon S3). In this example, the object is uploaded to Amazon S3 using [server-side encryption with AWS KMS-managed keys \(SSE-KMS\)](#) (p. 265). When you upload an object to Amazon S3 with SSE-KMS, you specify the KMS CMK to use for protecting the object. Amazon S3 uses the AWS KMS `GenerateDataKey` operation to request a unique data key for the object, and this request event is logged in CloudTrail with an entry similar to the following:

```
{
  "eventVersion": "1.02",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROACKCEVSQ6C2EXAMPLE:example-user",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admins/example-user",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2015-09-10T23:12:48Z"
      }
    }
  }
}
```

```
    },
    "sessionIssuer": {
      "type": "Role",
      "principalId": "AROACKCEVSQ6C2EXAMPLE",
      "arn": "arn:aws:iam::111122223333:role/Admins",
      "accountId": "111122223333",
      "userName": "Admins"
    }
  },
  "invokedBy": "internal.amazonaws.com"
},
"eventTime": "2015-09-10T23:58:18Z",
"eventSource": "kms.amazonaws.com",
"eventName": "GenerateDataKey",
"awsRegion": "us-west-2",
"sourceIPAddress": "internal.amazonaws.com",
"userAgent": "internal.amazonaws.com",
"requestParameters": {
  "encryptionContext": {"aws:s3:arn": "arn:aws:s3::example_bucket/example_object"},
  "keySpec": "AES_256",
  "keyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
},
"responseElements": null,
"requestID": "cea04450-5817-11e5-85aa-97ce46071236",
"eventID": "80721262-21a5-49b9-8b63-28740e7ce9c9",
"readOnly": true,
"resources": [{
  "ARN": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "accountId": "111122223333"
}],
"eventType": "AwsApiCall",
"recipientAccountId": "111122223333"
}
```

When you later download this object from Amazon S3, Amazon S3 sends a Decrypt request to AWS KMS to decrypt the object's data key using the specified CMK. When you do this, your CloudTrail log files include an entry similar to the following:

```
{
  "eventVersion": "1.02",
  "userIdentity": {
    "type": "AssumedRole",
    "principalId": "AROACKCEVSQ6C2EXAMPLE:example-user",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admins/example-user",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2015-09-10T23:12:48Z"
      }
    },
    "sessionIssuer": {
      "type": "Role",
      "principalId": "AROACKCEVSQ6C2EXAMPLE",
      "arn": "arn:aws:iam::111122223333:role/Admins",
      "accountId": "111122223333",
      "userName": "Admins"
    }
  },
  "invokedBy": "internal.amazonaws.com"
},
"eventTime": "2015-09-10T23:58:39Z",
"eventSource": "kms.amazonaws.com",
"eventName": "Decrypt",
```

```
"awsRegion": "us-west-2",

"userAgent": "internal.amazonaws.com",
"requestParameters": {
  "encryptionContext": {"aws:s3:arn": "arn:aws:s3:::example_bucket/example_object"}},
"responseElements": null,
"requestID": "db750745-5817-11e5-93a6-5b87e27d91a0",
"eventID": "ae551b19-8a09-4cfc-a249-205ddba330e3",
"readOnly": true,
"resources": [{
  "ARN": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
  "accountId": "111122223333"
}],
"eventType": "AwsApiCall",
"recipientAccountId": "111122223333"
}
```

All AWS KMS API activity is logged by CloudTrail. By evaluating these log entries, you might be able to determine the past usage of a particular CMK, and this might help you determine whether or not you want to delete it.

To see more examples of how AWS KMS API activity appears in your CloudTrail log files, go to [Logging AWS KMS API Calls with AWS CloudTrail \(p. 293\)](#). For more information about CloudTrail go to the [AWS CloudTrail User Guide](#).

# Using a Custom Key Store

AWS KMS supports [custom key stores \(p. 174\)](#) backed by [AWS CloudHSM clusters](#). When you create an AWS KMS [customer master key \(p. 2\)](#) (CMK) in a custom key store, AWS KMS generates and stores non-extractable key material for the CMK in an AWS CloudHSM cluster that you own and manage. When you use a CMK in a custom key store, the cryptographic operations are performed in the HSMs in the cluster. This feature combines the convenience and widespread integration of AWS KMS with the added control of an AWS CloudHSM cluster in your AWS account.

AWS KMS provides full console and API support for creating, using, and managing your custom key stores. When you create CMKs in a custom key store, you can use them just as you would any CMK. For example, you can use the CMKs to generate data keys and encrypt data. You can also use the CMKs in your custom key store with AWS services that support customer managed CMKs.

## Do I need a custom key store?

For most users, the default AWS KMS key store, which is protected by [FIPS 140-2 validated cryptographic modules](#), fulfills their security requirements. There is no need to add an extra layer of maintenance responsibility or a dependency on an additional service.

However, you might consider creating a custom key store if your organization has any of the following requirements:

- Key material cannot be stored in a shared environment.
- Key material must be backed up in multiple AWS Regions.
- Key material must be subject to a secondary, independent audit path.
- The HSMs that generate and store key material must be certified at [FIPS 140-2 Level 3](#).

## How do custom key stores work?

Each custom key store is associated with an AWS CloudHSM cluster in your AWS account. When you connect the custom key store to its cluster, AWS KMS creates the network infrastructure to support the connection. Then it logs into the key AWS CloudHSM client in the cluster using the credentials of a [dedicated crypto user \(p. 175\)](#) in the cluster.

You create and manage your custom key stores in AWS KMS and create and manage your HSM clusters in AWS CloudHSM. When you create customer master keys (CMKs) in an AWS KMS custom key store, you view and manage the CMKs in AWS KMS. But you can also view and manage their key material in AWS CloudHSM, just as you would do for other keys in the cluster.

You can [create symmetric CMKs \(p. 192\)](#) with key material generated by AWS KMS in your custom key store. Custom key stores do not support asymmetric CMKs or CMKs with [imported key material \(p. 147\)](#).

#### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

You can use the same techniques to view and manage the CMKs in your custom key store that you use for CMKs in the AWS KMS key store. You can control access with IAM and key policies, create tags and aliases, enable and disable the CMKs, and schedule key deletion. You can use the CMKs for cryptographic operations and use them with AWS services that integrate with AWS KMS. However, you cannot enable automatic key rotation and you cannot import key material into a CMK in a custom key store.

In addition, you have full control over the AWS CloudHSM cluster, including creating and deleting HSMs and managing backups. You can use the AWS CloudHSM client and supported software libraries to view, audit, and manage the key material for your CMKs. While the custom key store is disconnected, AWS KMS cannot access it, and users cannot use the CMKs in the custom key store for cryptographic operations. This added layer of control makes custom key stores a powerful solution for organizations that require it.

#### Where Do I Start?

To create and manage a custom key store, you use features of AWS KMS and AWS CloudHSM.

1. Start in AWS CloudHSM. [Create an active AWS CloudHSM cluster](#) or select an existing cluster. The cluster must have at least two active HSMs in different Availability Zones. Then create a [dedicated crypto user \(CU\) account \(p. 175\)](#) in that cluster for AWS KMS.
2. In AWS KMS, [create a custom key store \(p. 178\)](#) that is associated with your selected AWS CloudHSM cluster. AWS KMS provides [a complete management interface \(p. 182\)](#) that lets you create, view, edit, and delete your custom key stores.
3. When you're ready to use your custom key store, [connect it to its associated AWS CloudHSM cluster \(p. 186\)](#). AWS KMS creates the network infrastructure that it needs to support the connection. It then logs in to the cluster using the dedicated crypto user account credentials so it can generate and manage key material in the cluster.
4. Now, you can [create customer master keys \(CMKs\) in your custom key store \(p. 192\)](#). Just specify the custom key store when you create the CMK.

If you get stuck at any point, you can find help in the [Troubleshooting a Custom Key Store \(p. 202\)](#) topic. If your question is not answered, use the feedback link at the bottom of each page of this guide or post a question on the [AWS Key Management Service Discussion Forum](#).

### Quotas

There are no resource quotas for the number of custom key stores in an AWS account or Region. However, there are [quotas on the number of AWS CloudHSM clusters in each AWS region](#), and [request quotas \(p. 355\)](#) on the rate of cryptographic operations using the CMKs in each custom key store.

### Regions

AWS KMS supports custom key stores in all AWS Regions where both AWS KMS and AWS CloudHSM are available. For a list of AWS Regions that each service supports, see [AWS Key Management Service Endpoints and Quotas](#) and [AWS CloudHSM Endpoints and Quotas](#) in the *Amazon Web Services General Reference*.

- [CMKs in a Custom Key Store \(p. 176\)](#)

## AWS KMS Custom Key Store

A *key store* is a secure location for storing cryptographic keys. The default key store in AWS KMS also supports methods for generating and managing the keys that its stores. By default, the customer master keys (CMKs) that you create in AWS KMS are generated in and protected by hardware security modules (HSMs) that are [FIPS 140-2 validated cryptographic modules](#). The CMKs never leave the modules unencrypted.

However, if you require even more control of the HSMs, you can create a custom key store that is backed by [FIPS 140-2 Level 3 HSMs](#) in an [AWS CloudHSM](#) cluster that you own and manage.

A *custom key store* is an AWS KMS resource that is associated with an AWS CloudHSM cluster. When you create an AWS KMS CMK in your custom key store, AWS KMS generates a 256-bit, persistent, non-exportable Advanced Encryption Standard (AES) symmetric key in the associated AWS CloudHSM cluster. This key material never leaves your HSMs unencrypted. When you use a CMK in a custom key store, the cryptographic operations are performed in the HSMs in the cluster.

Custom key stores combine the convenient and comprehensive key management interface of AWS KMS with the additional controls provided by an AWS CloudHSM cluster in your AWS account. This integrated

feature lets you create, manage, and use CMKs in AWS KMS while maintaining full control of the HSMs that store their key material, including managing clusters, HSMs, and backups. You can use the AWS KMS console and APIs to manage the custom key store and its CMKs. You can also use the AWS CloudHSM console, APIs, client software, and associated software libraries to manage the associated cluster.

You can [view and manage \(p. 182\)](#) your custom key store, [edit its properties \(p. 184\)](#), and [connect and disconnect it \(p. 186\)](#) from its associated AWS CloudHSM cluster. If you need to [delete a custom key store \(p. 191\)](#), you must first delete the CMKs in the custom key store by scheduling their deletion and waiting until the grace period expires. Deleting the custom key store removes the resource from AWS KMS, but it does not affect your AWS CloudHSM cluster.

## AWS CloudHSM Cluster

Every AWS KMS custom key store is associated with one AWS CloudHSM cluster. When you create a customer master key (CMK) in your custom key store, AWS KMS creates its key material in the associated cluster. When you use a CMK in your custom key store, the cryptographic operation is performed in the associated cluster.

Each AWS CloudHSM cluster can be associated with only one custom key store. The cluster that you choose cannot be associated with another key store or share a backup history with an associated cluster. The cluster must be initialized and active, and it must be in the same AWS account and Region as the AWS KMS custom key store. You can create a new cluster or use an existing one. AWS KMS does not need exclusive use of the cluster. To create CMKs in the custom key store, its associated cluster it must contain at least two active HSMs. All other operations require only one HSM.

You specify the cluster when you create the custom key store, and you cannot change it. However, you can substitute any cluster that shares a backup history with the original cluster. This lets you delete the cluster, if necessary, and replace it with a cluster created from one of its backups. You retain full control of the associated AWS CloudHSM cluster so you can manage users and keys, create and delete HSMs, and use and manage backups.

When you are ready to use your custom key store, you connect it to its associated AWS CloudHSM cluster. You can [connect and disconnect your custom key store \(p. 186\)](#) at any time. When a custom key store is connected, you can create and use its CMKs. When it is disconnected, you can view and manage the custom key store and its CMKs. But you cannot create new CMKs or use the CMKs in the custom key store for cryptographic operations.

## kmsuser Crypto User

To create and manage key material in the associated AWS CloudHSM cluster on your behalf, AWS KMS uses a dedicated AWS CloudHSM [crypto user](#) (CU) in the cluster named `kmsuser`. The `kmsuser` CU is a standard CU account that is automatically synchronized to all HSMs in the cluster and is saved in cluster backups.

Before you create your custom key store, you [create a `kmsuser` CU account \(p. 179\)](#) in your AWS CloudHSM cluster using the `createUser` command in `cloudhsm_mgmt_util`. Then when you [create the custom key store \(p. 178\)](#), you provide the `kmsuser` account password to AWS KMS. When you [connect the custom key store \(p. 186\)](#), AWS KMS logs into the cluster as the `kmsuser` CU and rotates its password.

AWS KMS remains logged in as `kmsuser` as long as the custom key store is connected. You should not use this CU account for other purposes. However, you retain ultimate control of the `kmsuser` CU account. At any time, you can [find the key handles \(p. 201\)](#) of keys that `kmsuser` owns. If necessary, you can [disconnect the custom key store \(p. 186\)](#), change the `kmsuser` password, [log into the cluster as `kmsuser` \(p. 208\)](#), and view and manage the keys that `kmsuser` owns.

For instructions on creating your `kmsuser` CU account, see [Create the `kmsuser` Crypto User \(p. 179\)](#).

## CMKs in a Custom Key Store

You can use the AWS Management Console or AWS KMS API to create a [customer master key \(p. 2\)](#) (CMK) in a custom key store. You use the same technique that you would use on any AWS KMS CMK. The only difference is that you must identify the custom key store and specify that origin of the key material is the AWS CloudHSM cluster.

When you [create a CMK in a custom key store \(p. 192\)](#), AWS KMS creates the CMK in AWS KMS and it generates a 256-bit, persistent, non-exportable Advanced Encryption Standard (AES) symmetric backing key in its associated cluster. Although AWS CloudHSM supports symmetric and asymmetric keys of different types, AWS KMS and custom key stores only support AES symmetric keys.

You can view the CMKs in a custom key store in the AWS KMS console, and use the console options to display the custom key store ID. You can also use the [DescribeKey](#) operation to find the custom key store ID and AWS CloudHSM cluster ID.

The CMKs in a custom key store work just like any CMKs in AWS KMS. Authorized users need the same permissions to use and manage the CMKs. You use the same console procedures and API operations to view and manage the CMKs in a custom key store. These include enabling and disabling CMKs, creating and using tags and aliases, and setting and changing IAM and key policies. You can use the CMKs in a custom key store for cryptographic operations, and use them with [integrated AWS services \(p. 228\)](#) that support the use of customer managed CMKs. However, you cannot enable [automatic key rotation \(p. 142\)](#) or [import key material \(p. 147\)](#) into a CMK in a custom key store.

You also use the same process to [schedule deletion \(p. 202\)](#) of a CMK in a custom key store. After the waiting period expires, AWS KMS deletes the CMK from KMS. Then it makes a best effort to delete the key material for the CMK from the associated AWS CloudHSM cluster. However, you might need to manually [delete the orphaned key material \(p. 206\)](#) from the cluster and its backups.

## Controlling Access to Your Custom Key Store

You use IAM policies to control access to your AWS KMS custom key store and your AWS CloudHSM cluster. You can use IAM policies and key policies to control access to the customer master keys (CMKs) in your custom key store. We recommend that you provide users, groups, and roles only the permissions that they require for the tasks that they are likely to perform.

### Topics

- [Authorizing Custom Key Store Managers and Users \(p. 176\)](#)
- [Authorizing AWS KMS to Manage AWS CloudHSM and Amazon EC2 Resources \(p. 177\)](#)

## Authorizing Custom Key Store Managers and Users

When designing your custom key store, be sure that the principals who use and manage it have only the permissions that they require. The following list describes the minimum permissions required for custom key store managers and users.

- Principals who create and manage your custom key store require the following permission to use the custom key store API operations.
  - `cloudhsm:DescribeClusters`
  - `kms:CreateCustomKeyStore`
  - `kms:ConnectCustomKeyStore`
  - `kms:DisconnectCustomKeyStore`

- `kms:UpdateCustomKeyStore`
  - `kms>DeleteCustomKeyStore`
  - `kms:DescribeCustomKeyStores`
  - `iam:CreateServiceLinkedRole`
- Principals who create and manage the AWS CloudHSM cluster that is associated with your custom key store need permission to create and initialize an AWS CloudHSM cluster. This includes permission to create or use a virtual private cloud, create subnets, and create an Amazon EC2 instance. They might also need to create and delete HSMs, and manage backups. For lists of the required permissions, see [Restrict User Permissions to What's Necessary for AWS CloudHSM](#) in the *AWS CloudHSM User Guide*.
  - Principals who create and manage customer master keys (CMKs) in your custom key store require the same permissions as those who create and manage any CMK in AWS KMS. For example, those principals need an IAM policy with `kms:CreateKey` permission. No additional permissions are required. The [default key policy \(p. 51\)](#) for CMKs in a custom key store is identical to the default key policy for CMKs in AWS KMS.
  - Principals who use the CMKs in your custom key store for cryptographic operations need permission to perform the cryptographic operation with the CMK, such as `kms:Decrypt`. You can provide these permissions in an IAM or key policy. But, they do not need any additional permissions to use a CMK in a custom key store.

## Authorizing AWS KMS to Manage AWS CloudHSM and Amazon EC2 Resources

To support your custom key stores, AWS KMS needs permission to get information about your AWS CloudHSM clusters. It also needs permission to create the network infrastructure that connects your custom key store to its AWS CloudHSM cluster. To get these permissions, AWS KMS creates the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role in your AWS account. Users who create custom key stores must have the `iam:CreateServiceLinkedRole` permission that allows them to create service-linked roles.

### Topics

- [About the AWS KMS Service-Linked Role \(p. 177\)](#)
- [Create the Service-Linked Role \(p. 178\)](#)
- [Edit the Service-Linked Role Description \(p. 178\)](#)
- [Delete the Service-Linked Role \(p. 178\)](#)

## About the AWS KMS Service-Linked Role

A [service-linked role](#) is an IAM role that gives one AWS service permission to call other AWS services on your behalf. It's designed to make it easier for you to use the features of multiple integrated AWS services without having to create and maintain complex IAM policies.

For custom key stores, AWS KMS creates the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role with the **AWSKeyManagementServiceCustomKeyStoresServiceRolePolicy** policy. This policy grants the role the following permissions:

- [cloudhsm:DescribeClusters](#)
- [ec2:AuthorizeSecurityGroupIngress](#)
- [ec2:CreateNetworkInterface](#)
- [ec2:CreateSecurityGroup](#)
- [ec2>DeleteSecurityGroup](#)
- [ec2:DescribeSecurityGroups](#)
- [ec2:RevokeSecurityGroupEgress](#)

Because the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role trusts only `cks.kms.amazonaws.com`, only AWS KMS can assume this service-linked role. This role is limited to the operations that AWS KMS needs to view your AWS CloudHSM clusters and to connect a custom key store to its associated AWS CloudHSM cluster. It does not give AWS KMS any additional permissions. For example, AWS KMS does not have permission to create, manage, or delete your AWS CloudHSM clusters, HSMs, or backups.

### Regions

Like the custom key stores feature, the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** role is supported in all AWS Regions where AWS KMS and AWS CloudHSM are available. For a list of AWS Regions that each service supports, see [AWS Key Management Service Endpoints and Quotas](#) and [AWS CloudHSM Endpoints and Quotas](#) in the *Amazon Web Services General Reference*.

For more information about how AWS services use service-linked roles, see [Using Service-Linked Roles](#) in the IAM User Guide.

## Create the Service-Linked Role

AWS KMS automatically creates the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role in your AWS account when you create a custom key store, if the role does not already exist. You cannot create or re-create this service-linked role directly.

## Edit the Service-Linked Role Description

You cannot edit the role name or the policy statements in the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role, but you can edit role description. For instructions, see [Editing a Service-Linked Role](#) in the *IAM User Guide*.

## Delete the Service-Linked Role

AWS KMS does not delete the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role from your AWS account. If you have [deleted all of your custom key stores \(p. 190\)](#) and do not plan to create any new ones, you no longer need this service-linked role. AWS KMS does not assume this role or use its permissions unless you have active custom key stores. However, there is currently no procedure for deleting the **AWSServiceRoleForKeyManagementServiceCustomKeyStores** service-linked role.

# Creating a Custom Key Store

You can create one or several [custom key stores \(p. 174\)](#) in your account. Each custom key store is associated with one AWS CloudHSM cluster in the same AWS Region. Before you create your custom key store, you need to [assemble the prerequisites \(p. 179\)](#). Then, before you can use your custom key store, you must [connect it \(p. 186\)](#) to its AWS CloudHSM cluster.

### Tip

You do not have to connect your custom key store immediately. You can leave it in a disconnected state until you are ready to use it. However, to verify that it is configured properly, you might want to [connect it \(p. 186\)](#), [view its connection status \(p. 182\)](#), and then [disconnect it \(p. 186\)](#).

### Topics

- [Assemble the Prerequisites \(p. 179\)](#)
- [Create a Custom Key Store \(Console\) \(p. 180\)](#)
- [Create a Custom Key Store \(API\) \(p. 181\)](#)

## Assemble the Prerequisites

Each AWS KMS custom key store is backed by an AWS CloudHSM cluster. To create a custom key store, you must specify an active AWS CloudHSM cluster that is not already associated with another key store. You also need to create a dedicated crypto user (CU) in the cluster's HSMs that AWS KMS can use to create and manage keys on your behalf.

Before you create a custom key store, do the following:

### Select an AWS CloudHSM Cluster

Every custom key store is [associated with exactly one AWS CloudHSM cluster \(p. 175\)](#). When you create a [customer master key \(p. 2\)](#) (CMK) in your custom key store, AWS KMS creates the CMK metadata, such as an ID and Amazon Resource Name (ARN) in AWS KMS. It then creates the key material in the HSMs of the associated cluster. You can [create a new AWS CloudHSM cluster](#) or use an existing one. AWS KMS does not require exclusive access to the cluster.

The AWS CloudHSM cluster that you select is permanently associated with the custom key store. After you create the custom key store, you can [change the cluster ID \(p. 184\)](#) of the associated cluster, but the cluster that you specify must share a backup history with the original cluster. To use an unrelated cluster, you need to create a new custom key store.

The AWS CloudHSM cluster that you select must have the following characteristics:

- **The cluster must be active.**

You must create the cluster, initialize it, install the AWS CloudHSM client software for your platform, and then activate the cluster. For detailed instructions, see the [Getting Started](#) section of the *AWS CloudHSM User Guide*.

- **The cluster must be in the same account and Region** as the AWS KMS custom key store. You cannot associate a custom key store in one region with a cluster in a different region. To create a multi-region key infrastructure, you must create key stores and clusters in each region.
- **The cluster cannot be associated with** another custom key store in the account. Each custom key store must be associated with a different AWS CloudHSM cluster. You cannot specify a cluster that is already associated with a custom key store or a cluster that shares a backup history with an associated cluster. Clusters that share a backup history have the same cluster certificate. To view the cluster certificate of a cluster, use the AWS CloudHSM console or the [DescribeClusters](#) operation.
- The cluster must be configured with private subnets in **at least two Availability Zones** in the Region. Because AWS CloudHSM is not supported in all Availability Zones, we recommend that you

create private subnets in all Availability Zones in the region. You cannot reconfigure the subnets for an existing cluster, but you can [create a cluster from a backup](#) with different subnets in the cluster configuration.

- The [security group for the cluster](#) (cloudhsm-cluster-*<cluster-id>*-sg) must include inbound rules and outbound rules that allow TCP traffic on ports 2223-2225. The **Source** in the inbound rules and the **Destination** in the outbound rules must match the security group ID. These rules are set by default when you create the cluster. Do not delete or change them.
- **The cluster must contain at least two active HSMS** in different Availability Zones. To verify the number of HSMS, use the AWS CloudHSM console or the [DescribeClusters](#) operation. If necessary, you can [add an HSM](#).

### Find the Trust Anchor Certificate

When you create a custom key store, you must upload the trust anchor certificate for the AWS CloudHSM cluster to AWS KMS. AWS KMS needs the trust anchor certificate to connect the custom key store to the cluster.

Every active AWS CloudHSM cluster has a *trust anchor certificate*. When you [initialize the cluster](#), you generate this certificate, save it in the `customerCA.crt` file, and copy it to hosts that connect to the cluster.

### Create the `kmsuser` Crypto User for AWS KMS

To administer your custom key store, AWS KMS logs into the [kmsuser crypto user \(p. 175\)](#) (CU) account in the selected cluster. Before you create your custom key store, you must create the `kmsuser` CU. Then when you create your custom key store, you provide the password for `kmsuser` to AWS KMS. AWS KMS rotates the `kmsuser` password whenever you connect the custom key store to its associated AWS CloudHSM cluster.

#### Important

Do not specify the 2FA option when you create the `kmsuser` CU. If you do, AWS KMS cannot log in and your custom key store cannot be connected to this AWS CloudHSM cluster. Once you specify 2FA, you cannot undo it. Instead, you must delete the CU and recreate it.

To create the `kmsuser` CU, use the following procedure.

1. Start `cloudhsm_mgmt_util` as described in the [Prepare to run cloudhsm\\_mgmt\\_util](#) section of the *AWS CloudHSM User Guide*.
2. Use the [createUser](#) command in `cloudhsm_mgmt_util` to create a CU named `kmsuser`. The password must consist of 7-32 alphanumeric characters. It is case-sensitive and cannot contain any special characters.

For example, the following example command creates a `kmsuser` CU with a password of `kmsPswd`.

```
aws-cloudhsm> createUser CU kmsuser kmsPswd
```

## Create a Custom Key Store (Console)

When you create a [custom key store \(p. 174\)](#) in the AWS Management Console, you can add and create the [prerequisites \(p. 179\)](#) as part of your workflow. However, the process is quicker when you have assembled them in advance.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.
4. Choose **Create key store**.
5. Enter a friendly name for the custom key store. The name must be unique in the account.
6. Select [an AWS CloudHSM cluster \(p. 175\)](#) for the custom key store. Or, to create a new AWS CloudHSM cluster, choose the **Create an AWS CloudHSM cluster** link.

The cluster must [fulfill the requirements \(p. 179\)](#) for association with a custom key store. The menu displays custom key stores in your account and region that are not already associated with a custom key store.

7. Choose **Upload file**, and then upload the trust anchor certificate for the AWS CloudHSM cluster that you chose. This is the `customerCA.crt` file that you created when you [initialized the cluster](#).
8. Enter the password of [the kmsuser crypto user \(p. 175\)](#) (CU) that you created in the selected cluster.
9. Choose **Create**.

When the procedure is successful, the new custom key store appears in the list of custom key stores in the account and Region. If it is unsuccessful, an error message appears that describes the problem and provides help on how to fix it. If you need more help, see [Troubleshooting a Custom Key Store \(p. 202\)](#).

**Next:** New custom key stores are not automatically connected. Before you can create customer master keys (CMKs) in the custom key store, you must [connect the custom key store \(p. 186\)](#) to its associated AWS CloudHSM cluster.

## Create a Custom Key Store (API)

The `CreateCustomKeyStore` operation creates a new [custom key store \(p. 174\)](#) that is associated with an AWS CloudHSM cluster in the account and Region. These examples use the AWS Command Line Interface (AWS CLI), but you can use any supported programming language.

The `CreateCustomKeyStore` operation requires the following parameter values.

- `CustomKeyName` – A friendly name for the custom key store that is unique in the account.
- `CloudHsmClusterId` – The cluster ID of a cluster that [fulfills the requirements \(p. 179\)](#) for association with a custom key store.
- `KeyStorePassword` – The password of `kmsuser` CU account in the specified cluster.
- `TrustAnchorCertificate` – The content of the `customerCA.crt` file that you created when you [initialized the cluster](#).

The following example uses a fictitious cluster ID. Before running the command, replace it with a valid cluster ID.

```
$ aws kms create-custom-key-store
  --custom-key-store-name ExampleKeyStore \
  --cloud-hsm-cluster-id cluster-1a23b4cdefg \
  --key-store-password kmsPswd \
  --trust-anchor-certificate <certificate-goes-here>
```

If you are using the AWS CLI, you can specify the trust anchor certificate file, instead of its contents. In the following example, the `customerCA.crt` file is in the root directory.

```
$ aws kms create-custom-key-store
    --custom-key-store-name ExampleKeyStore \
    --cloud-hsm-cluster-id cluster-1a23b4cdefg \
    --key-store-password kmsPswd \
    --trust-anchor-certificate file://customerCA.crt
```

When the operation is successful, `CreateCustomKeyStore` returns the custom key store ID, as shown in the following example response.

```
{
  "CustomKeyStoreId": cks-1234567890abcdef0
}
```

If the operation fails, correct the error indicated by the exception, and try again. For additional help, see [Troubleshooting a Custom Key Store](#) (p. 202).

Next, to use the custom key store, [connect it to its AWS CloudHSM cluster](#) (p. 186).

## Managing a Custom Key Store

Using the AWS Management Console and the AWS KMS API, you can manage a custom key store. For example, you can view a custom key store, edit its properties, connect and disconnect it from its associated AWS CloudHSM cluster, and delete the custom key store.

### Topics

- [Viewing a Custom Key Store](#) (p. 182)
- [Editing Custom Key Store Settings](#) (p. 184)
- [Connecting and Disconnecting a Custom Key Store](#) (p. 186)
- [Deleting a Custom Key Store](#) (p. 190)

## Viewing a Custom Key Store

You can view the custom key stores in each account and region by using the AWS Management Console or the AWS KMS API.

For help with viewing the CMKs in your custom key store, see [Viewing CMKs in a Custom Key Store](#) (p. 196).

### Topics

- [View a Custom Key Store \(Console\)](#) (p. 182)
- [View a Custom Key Store \(API\)](#) (p. 183)

## View a Custom Key Store (Console)

When you view the custom key stores in the AWS Management Console, you can see the following:

- The custom key store name
- The ID of associated AWS CloudHSM cluster
- The number of HSMs in the cluster
- The current connection status

A connection status of **Disconnected** indicates that the custom key store is new and has never been connected, or it was intentionally [disconnected from its AWS CloudHSM cluster \(p. 186\)](#). However, if your attempts to use a CMK in a connected custom key store fail, that might indicate a problem with the custom key store or its AWS CloudHSM cluster. For help, see [How to Fix a Failing CMK \(p. 203\)](#).

To view the custom key stores in a given account and Region, use the following procedure.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.

To customize the display, click the gear icon that appears below the **Create key store** button.

## View a Custom Key Store (API)

To view your custom key stores, use the [DescribeCustomKeyStores](#) operation. By default, this operation returns all custom key stores in the account and Region. But you can use either the `CustomKeyId` or `CustomKeyName` parameter (but not both) to limit the output to a particular custom key store. The output consists of the custom key store ID and name, the ID of the associated AWS CloudHSM cluster, and the connection state. If the connection state indicates an error, the output also includes an error code that describes the reason for the error.

The examples in this section use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

For example, the following command returns all custom key stores in the account and Region. You can use the `Limit` and `Marker` parameters to page through the custom key stores in the output.

```
$ aws kms describe-custom-key-stores
```

The following example command uses the `CustomKeyName` parameter to get only the custom key store with the `ExampleKeyStore` friendly name. You can use either the `CustomKeyName` or `CustomKeyId` parameter (but not both) in each command.

The following example output represents a custom key store that is connected to its AWS CloudHSM cluster. The `ConnectionState` element corresponds to the `Status` field in the console.

```
$ aws kms describe-custom-key-stores --custom-key-store-name ExampleKeyStore
{
  "CustomKeyStores": [
    {
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "ConnectionState": "CONNECTED",
      "CreationDate": "1.499288695918E9",
      "CustomKeyId": "cks-1234567890abcdef0",
      "CustomKeyName": "ExampleKeyStore",
      "TrustAnchorCertificate": "<certificate appears here>"
    }
  ]
}
```

A `ConnectionState` of `Disconnected` indicates that a custom key store has never been connected or it was intentionally [disconnected from its AWS CloudHSM cluster \(p. 186\)](#). However, if attempts to use a CMK in a connected custom key store fail, that might indicate a problem with the custom key store or its AWS CloudHSM cluster. For help, see [How to Fix a Failing CMK \(p. 203\)](#).

If the `ConnectionState` of the custom key store is `FAILED`, the `DescribeCustomKeyStores` response includes a `ConnectionErrorCode` element that explains the reason for the error.

For example, in the following output, the `INVALID_CREDENTIALS` value indicates that the custom key store connection failed because the `kmsuser` password is invalid (p. 205). For help with this and other connection error failures, see [Troubleshooting a Custom Key Store](#) (p. 202).

```
$ aws kms describe-custom-key-stores --custom-key-store-id cks-1234567890abcdef0
{
  "CustomKeyStores": [
    {
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "ConnectionErrorCode": "INVALID_CREDENTIALS",
      "ConnectionState": "FAILED",
      "CustomKeyId": "cks-1234567890abcdef0",
      "CustomKeyName": "ExampleKeyStore",
      "CreationDate": "1.499288695918E9",
      "TrustAnchorCertificate": "<certificate appears here>"
    }
  ]
}
```

## Editing Custom Key Store Settings

You can change the settings of an existing [custom key store](#) (p. 174). The custom key store must be disconnected from its AWS CloudHSM cluster.

To edit custom key store settings:

1. [Disconnect the custom key store](#) (p. 186) from its AWS CloudHSM cluster. While the custom key store is disconnected, you cannot create [customer master keys](#) (p. 2) (CMKs) in the custom key store and you cannot use the CMKs it contains for cryptographic operations.
2. Edit one or more of the custom key store settings.
3. [Reconnect the custom key store](#) (p. 186) to its AWS CloudHSM cluster.

You can edit the following settings in a custom key store:

### The friendly name of the custom key store.

Enter a new friendly name. The new name must be unique in your AWS account.

### The cluster ID of the associated AWS CloudHSM cluster.

Edit this value to substitute a related AWS CloudHSM cluster for the original one. You can use this feature to repair a custom key store if its AWS CloudHSM cluster becomes corrupted or is deleted.

Specify an AWS CloudHSM cluster that shares a backup history with the original cluster and [fulfills the requirements](#) (p. 179) for association with a custom key store, including two active HSMs in different Availability Zones. Clusters that share a backup history have the same cluster certificate. To view the cluster certificate of a cluster, use the [DescribeClusters](#) operation. You cannot use the edit feature to associate the custom key store with an unrelated AWS CloudHSM cluster.

### The current password of the `kmsuser` crypto user (p. 175) (CU).

Tells AWS KMS the current password of the `kmsuser` CU in the AWS CloudHSM cluster. This action does not change the password of the `kmsuser` CU in the AWS CloudHSM cluster.

If you change the password of the `kmsuser` CU in the AWS CloudHSM cluster, use this feature to tell AWS KMS the new `kmsuser` password. Otherwise, AWS KMS cannot log into the cluster and all attempts to connect the custom key store to the cluster fail.

## Topics

- [Edit a Custom Key Store \(Console\) \(p. 185\)](#)
- [Edit a Custom Key Store \(API\) \(p. 185\)](#)

## Edit a Custom Key Store (Console)

When you edit the custom key store, you can change any or of the configurable values.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.
4. Choose the custom key store you want to edit.
5. If the value in the **Status** column is not **DISCONNECTED**, you must disconnect the custom key store before you can edit it. From the **Key store actions** menu, select **Disconnect custom key store**.
6. From the **Key store actions** menu, select **Edit custom key store settings**.
7. Do one or more of the following actions.
  - Type a new friendly name for the custom key store.
  - Type the cluster ID of a related AWS CloudHSM cluster.
  - Type the current password of the `kmsuser` crypto user in the associated AWS CloudHSM cluster.
8. Choose **Save**.

When the procedure is successful, a message describes the settings that you edited. When it is unsuccessful, an error message appears that describes the problem and provides help on how to fix it. If you need more help, see [Troubleshooting a Custom Key Store \(p. 202\)](#).

9. [Reconnect the custom key store. \(p. 186\)](#)

To use the custom key store, you must reconnect it after editing. You can leave the custom key store disconnected. But while it is disconnected, you cannot create CMKs in the custom key store or use the CMKs in the custom key store in cryptographic operations.

## Edit a Custom Key Store (API)

To change the properties of a custom key store, use the [UpdateCustomKeyStore](#) operation. You can change multiple properties of a custom key store in the same command. If the operation is successful, AWS KMS returns an HTTP 200 response and a JSON object with no properties.

The examples in this section use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

Begin by using [DisconnectCustomKeyStore](#) to [disconnect the custom key store \(p. 186\)](#) from AWS KMS. Replace the example custom key store ID, `cks-1234567890abcdef0`, with an actual ID.

```
$ aws kms disconnect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

The first example uses [UpdateCustomKeyStore](#) to change the friendly name of the custom key store to `DevelopmentKeys`. The command uses the `CustomKeyStoreId` parameter to identify the custom key store and the `CustomKeyStoreName` to specify the new name for the custom key store.

```
$ aws kms update-custom-key-store --custom-key-store-id cks-1234567890abcdef0 --new-custom-key-store-name DevelopmentKeys
```

The following example changes the cluster that is associated with a custom key store to another backup of the same cluster. The command uses the `CustomKeyStoreId` parameter to identify the custom key store and the `CloudHsmClusterId` parameter to specify the new cluster ID.

```
$ aws kms update-custom-key-store --custom-key-store-id cks-1234567890abcdef0 --cloud-hsm-cluster-id cluster-1a23b4cdefg
```

The following example tells AWS KMS that the current `kmsuser` password is `ExamplePassword`. The command uses the `CustomKeyStoreId` parameter to identify the custom key store and the `KeyStorePassword` parameter to specify the current password.

```
$ aws kms update-custom-key-store --custom-key-store-id cks-1234567890abcdef0 --key-store-password ExamplePassword
```

The final command reconnects the custom key store to AWS KMS. You can leave the custom key store in the disconnected state, but you must connect it before you can create new CMKs or use existing CMKs for cryptographic operations. Replace the example custom key store ID with an actual ID.

```
$ aws kms connect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

## Connecting and Disconnecting a Custom Key Store

New custom key stores are not connected. Before you can create and use customer master keys (CMKs) in your custom key store, you need to connect it to its associated AWS CloudHSM cluster. You can connect and disconnect your custom key store at any time, and [view its connection status](#) (p. 182).

You are not required to connect your custom key store. You can leave a custom key store in a disconnected state indefinitely and connect it only when you need to use it. However, you might want to test the connection periodically to verify that the settings are correct and it can be connected.

### Note

Custom key stores have a `DISCONNECTED` status only when the key store has never been connected or you explicitly disconnect it. If your custom key store status is `CONNECTED` but you are having trouble using it, make sure that its associated AWS CloudHSM cluster is active and contains at least one active HSMs. For help with connection failures, see [the section called "Troubleshooting a Custom Key Store"](#) (p. 202).

### Connecting a Custom Key Store

When you connect a custom key store, AWS KMS finds the associated AWS CloudHSM cluster, connects to it, logs into the AWS CloudHSM client as the `kmsuser` [crypto user](#) (p. 175) (CU), and then rotates the `kmsuser` password. AWS KMS remains logged into the AWS CloudHSM client as long as the custom key store is connected.

To establish the connection, AWS KMS creates a [security group](#) named `kms-<custom key store ID>` in the virtual private cloud (VPC) of the cluster. The security group has a single rule that allows inbound traffic from the cluster security group. AWS KMS also creates an [elastic network interface](#) (ENI) in each Availability Zone of the private subnet for the cluster. AWS KMS adds the ENIs to the `kms-<cluster ID>` security group and the security group for the cluster. The description of each ENI is `KMS managed ENI for cluster <cluster-ID>`.

The connection process can take an extended amount of time to complete; up to 20 minutes.

Before you connect the custom key store, verify that it meets the requirements.

- Its associated AWS CloudHSM cluster must contain at least one active HSM. To find the number of HSMs in the cluster, view the cluster in the AWS CloudHSM console or use the [DescribeClusters](#) operation. If necessary, you can [add an HSM](#).

- The cluster must have a [kmsuser crypto user \(p. 180\)](#) (CU) account, but that CU cannot be logged into the cluster when you connect the custom key store. For help with logging out, see [How to Log Out and Reconnect \(p. 209\)](#).
- The connection status of the custom key store cannot be `DISCONNECTING` or `FAILED`. You can [view the connection status \(p. 182\)](#) in the console or by using the `DescribeCustomKeyStores` operation. If the connection status is `FAILED`, disconnect the custom key store, and then connect it.

When your custom key store is connected, you can [create CMKs in it \(p. 192\)](#) and use existing CMKs in cryptographic operations.

### Disconnecting a Custom Key Store

When you disconnect a custom key store, AWS KMS logs out of the AWS CloudHSM client, disconnects from the associated AWS CloudHSM cluster, and removes the network infrastructure that it created to support the connection.

While a custom key store is disconnected, you can manage the custom key store and its customer master keys (CMKs), but you cannot create or use CMKs in the custom key store. The status of the key store is `DISCONNECTED` and the [key state \(p. 223\)](#) of CMKs in the custom key store is `Unavailable`, unless they are `PendingDeletion`. You can reconnect the custom key store at any time.

#### Note

While a custom key store is disconnected, all attempts to create customer master keys (CMKs) in the custom key store or to use existing CMKs in cryptographic operations will fail. This action can prevent users from storing and accessing sensitive data.

To better estimate the effect of disconnecting your key store, [identify the CMKs \(p. 199\)](#) in the custom key store and [determine their past use \(p. 169\)](#).

You might disconnect the custom key store for reasons such as the following:

- **To rotate of the `kmsuser` password.** AWS KMS changes the `kmsuser` password each time that it connects to the AWS CloudHSM cluster. To force a password rotation, just disconnect and reconnect.
- **To audit the key material** for the CMKs in the AWS CloudHSM cluster. When you disconnect the custom key store, AWS KMS logs out of the [kmsuser crypto user \(p. 175\)](#) account in the AWS CloudHSM client. This allows you to log into the cluster as the `kmsuser` CU and audit and manage the key material for the CMK.
- **To immediately disable all CMKs** in the custom key store. You can [disable and re-enable CMKs \(p. 41\)](#) in a custom key store by using the AWS Management Console or the `DisableKey` operation. These operations complete quickly, but they act on one CMK at a time. Disconnecting immediately changes the key state of all CMKs in the custom key to `Unavailable`, which prevents them from being used in any cryptographic operation.
- **To repair a failed connection attempt.** If an attempt to connect a custom key store fails (the connection status of the custom key store is `FAILED`), you must disconnect the custom key store before you try to connect it again.

### Topics

- [Connect a Custom Key Store \(Console\) \(p. 188\)](#)
- [Connect a Custom Key Store \(API\) \(p. 188\)](#)

- [Disconnect a Custom Key Store \(Console\) \(p. 189\)](#)
- [Disconnect a Custom Key Store \(API\) \(p. 189\)](#)

## Connect a Custom Key Store (Console)

To connect a custom key store in the AWS Management Console, begin by selecting the custom key store from the **Custom key stores** page. The process can take up to 20 minutes to complete.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.
4. Choose the custom key store you want to connect.
5. If the status of the custom key store is **FAILED**, you must [disconnect the custom key store \(p. 189\)](#) before you connect it.
6. From the **Key store actions** menu, select **Connect custom key store**.

AWS KMS begins the process of connecting your custom key store. It finds the associated AWS CloudHSM cluster, builds the required network infrastructure, connects to it, logs into the AWS CloudHSM cluster as the `kmsuser` CU, and rotates the `kmsuser` password. When the operation completes, the connection state changes to **CONNECTED**.

If the operation fails, an error message appears that describes the reason for the failure. Before you try to connect again, [view the connection status \(p. 182\)](#) of your custom key store. If it is **FAILED**, you must [disconnect the custom key store \(p. 189\)](#) before you connect it again. If you need help, see [Troubleshooting a Custom Key Store \(p. 202\)](#).

**Next:** [Create CMKs in a custom key store \(p. 192\)](#).

## Connect a Custom Key Store (API)

To connect a disconnected custom key store, use the `ConnectCustomKeyStore` operation. The associated AWS CloudHSM cluster must contain at least one active HSM and the connection status cannot be **FAILED**.

The connection process takes an extended amount of time to complete; up to 20 minutes. Unless it fails quickly, the operation returns an HTTP 200 response and a JSON object with no properties. However, this initial response does not indicate that the connection was successful. To determine the connection status of the custom key store, use the `DescribeCustomKeyStores` operation.

The examples in this section use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

To identify the custom key store, use the custom key store ID. You can find the ID on the **Custom key stores** page in the console or by using the `DescribeCustomKeyStores` operation. Before running this example, replace the example ID with a valid one.

```
$ aws kms connect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

To verify that the custom key store is connected, use the `DescribeCustomKeyStores` operation. By default, this operation returns all custom keys stores in your account and Region. But you can use either the `CustomKeyId` or `CustomKeyName` parameter (but not both) to limit the response to

particular custom key stores. The `ConnectionState` value of `CONNECTED` indicates that the custom key store is connected to its AWS CloudHSM cluster.

```
$ aws kms describe-custom-key stores --custom-key-store-id cks-1234567890abcdef0
{
  "CustomKeyStores": [
    {
      "CustomKeyStoreId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "TrustAnchorCertificate": "<certificate string appears here>",
      "CreationDate": "1.499288695918E9",
      "ConnectionState": "CONNECTED"
    }
  ],
}
```

If the `ConnectionState` value is failed, the `ConnectionErrorCode` element indicates the reason for the failure. In this case, AWS KMS could not find an AWS CloudHSM cluster in your account with the cluster ID `cluster-1a23b4cdefg`. If you deleted the cluster, you can [restore it from a backup](#) of the original cluster and then [edit the cluster ID \(p. 184\)](#) for the custom key store.

```
$ aws kms describe-custom-key stores --custom-key-store-id cks-1234567890abcdef0
{
  "CustomKeyStores": [
    {
      "CustomKeyStoreId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "TrustAnchorCertificate": "<certificate string appears here>",
      "CreationDate": "1.499288695918E9",
      "ConnectionState": "FAILED",
      "ConnectionErrorCode": "CLUSTER_NOT_FOUND"
    }
  ],
}
```

**Next:** [Create CMKs in a custom key store \(p. 192\)](#).

## Disconnect a Custom Key Store (Console)

To disconnect a connected custom key store in the AWS Management Console, begin by selecting the custom key store from the **Custom Key Stores** page.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.
4. Choose the custom key store you want to disconnect.
5. From the **Key store actions** menu, select **Disconnect custom key store**.

When the operation completes, the connection state changes from **DISCONNECTING** to **DISCONNECTED**. If the operation fails, an error message appears that describes the problem and provides help on how to fix it. If you need more help, see [Troubleshooting a Custom Key Store \(p. 202\)](#).

## Disconnect a Custom Key Store (API)

To disconnect a connected custom key store, use the `DisconnectCustomKeyStore` operation. If the operation is successful, AWS KMS returns an HTTP 200 response and a JSON object with no properties.

The examples in this section use the [AWS Command Line Interface \(AWS CLI\)](#), but you can use any supported programming language.

This example disconnects a custom key store. Before running this example, replace the example ID with a valid one.

```
$ aws kms disconnect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

To verify that the custom key store is disconnected, use the [DescribeCustomKeyStores](#) operation. By default, this operation returns all custom keys stores in your account and Region. But you can use either the `CustomKeyStoreId` and `CustomKeyStoreName` parameter (but not both) to limit the response to particular custom key stores. The `ConnectionState` value of `DISCONNECTED` indicates that the custom key store is not connected to its AWS CloudHSM cluster.

```
$ aws kms describe-custom-key stores --custom-key-store-id cks-1234567890abcdef0
{
  "CustomKeyStores": [
    {
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "ConnectionState": "DISCONNECTED",
      "CreationDate": "1.499288695918E9",
      "CustomKeyStoreId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "TrustAnchorCertificate": "<certificate string appears here>"
    }
  ],
}
```

## Deleting a Custom Key Store

When you delete a custom key store, AWS KMS deletes all metadata about the custom key store from KMS, including information about its association with an AWS CloudHSM cluster. This operation does not affect the AWS CloudHSM cluster, its HSMs, or its users. You can create a new custom key store that is associated with the specified cluster, but you cannot undo the delete operation.

You can only delete a custom key store that is disconnected from AWS KMS and does not contain any customer master keys (CMKs). Before you delete a custom key store, do the following.

- Verify that you will never need to use any of the CMKs in the key store for any cryptographic operations. Then [schedule deletion \(p. 202\)](#) of all of the CMKs from the key store. For help finding the CMKs in a custom key store, see [Find the CMKs in a Custom Key Store \(p. 199\)](#).
- Confirm that all CMKs have been deleted. To view the CMKs in a custom key store, see [Viewing CMKs in a Custom Key Store \(p. 196\)](#).
- [Disconnect the custom key store \(p. 186\)](#) from AWS KMS.

Instead of deleting the custom key store, consider [disconnecting it \(p. 186\)](#) from its associated AWS CloudHSM cluster. While a custom key store is disconnected, you can manage the custom key store and its customer master keys (CMKs). But you cannot create or use CMKs in the custom key store. You can reconnect the custom key store at any time.

If you have deleted all custom key stores from all Regions of your AWS account and you do not plan to create any more, you should [delete the service-linked role \(p. 177\)](#) that AWS KMS uses for custom key stores.

### Topics

- [Delete a Custom Key Store \(Console\) \(p. 191\)](#)
- [Delete a Custom Key Store \(API\) \(p. 191\)](#)

## Delete a Custom Key Store (Console)

To delete a custom key store in the AWS Management Console, begin by selecting the custom key store from the **Custom key stores** page.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Custom key stores**.
4. Find the row that represents the custom key store that you want to remove. If the status of the custom key store is not **DISCONNECTED**, you must [disconnect the custom key store \(p. 186\)](#) before you delete the custom key store.
5. From the **Key store actions** menu, select **Delete custom key store**.

When the operation completes, a success message appears and the custom key store no longer appears in the custom key store list. If the operation is unsuccessful, an error message appears that describes the problem and provides help on how to fix it. If you need more help, see [Troubleshooting a Custom Key Store \(p. 202\)](#).

## Delete a Custom Key Store (API)

To delete a custom key store, use the [DeleteCustomKeyStore](#) operation. If the operation is successful, AWS KMS returns an HTTP 200 response and a JSON object with no properties.

To begin, verify that the custom key store does not contain any AWS KMS customer master keys (CMKs). You cannot delete a custom key store that contains CMKs. The first example command uses [ListKeys](#) and [DescribeKey](#) to search for AWS KMS customer master keys in the custom key store with the `cks-1234567890abcdef0` fictitious key store ID. In this case, the command does not return any CMKs. If it does, use the [ScheduleKeyDeletion](#) operation to schedule deletion of each of the CMKs.

Bash

```
for key in $(aws kms list-keys --query 'Keys[*].KeyId' --output text) ;  
do aws kms describe-key --key-id $key |  
grep '"CustomKeyStoreId": "cks-1234567890abcdef0"' --context 100; done
```

PowerShell

```
PS C:\> (Get-KMSKeyList).KeyArn | foreach {Get-KMSKey -KeyId $_} | where  
CustomKeyStoreId -eq 'cks-1234567890abcdef0'
```

Next, disconnect the custom key store. This example command uses the [DisconnectCustomKeyStore](#) operation to disconnect the custom key store from its AWS CloudHSM cluster. Before running this command, replace the example custom key store ID with a valid one.

Bash

```
$ aws kms disconnect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

PowerShell

```
PS C:\> Disconnect-KMSCustomKeyStore -CustomKeyStoreId cks-1234567890abcdef0
```

After the custom key store is disconnected, you can use the [DeleteCustomKeyStore](#) operation to delete it.

Bash

```
$ aws kms delete-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

PowerShell

```
PS C:\> Remove-KMSCustomKeyStore -CustomKeyStoreId cks-1234567890abcdef0
```

## Managing CMKs in a Custom Key Store

You can create, view, manage, use, and schedule deletion of the customer master keys (CMKs) in a custom key store. The procedures that you use are very similar to those that you use for CMKs in AWS KMS. The only difference is that you specify a custom key store when you create the CMK. Then, AWS KMS creates non-extractable key material for the CMK in the AWS CloudHSM cluster that is associated with the custom key store. When you use a CMK in a custom key store, the cryptographic operations are performed in the HSMs in the cluster.

In addition to the procedures discussed in this section, you can do the following with CMKs in a custom key store:

- Use key policies, IAM policies, and grants to [authorize access \(p. 46\)](#) to the CMK.
- Assign [tags \(p. 39\)](#) to the CMKs and create [aliases \(p. 344\)](#) that refer to the CMKs.
- Use the CMKs for cryptographic operations, including encrypting, decrypting, re-encrypting, and generating data keys. For details, see [AWS Key Management Service API Reference](#).
- Use the CMKs with [AWS services that integrate with AWS KMS \(p. 228\)](#) and support customer managed CMKs.
- Track your CMK use in [AWS CloudTrail logs \(p. 293\)](#) and [Amazon CloudWatch monitoring tools \(p. 286\)](#).

However, you cannot import key material into a CMK in a custom key store.

### Topics

- [Creating CMKs in a Custom Key Store \(p. 192\)](#)
- [Viewing CMKs in a Custom Key Store \(p. 196\)](#)
- [Using CMKs in a Custom Key Store \(p. 197\)](#)
- [Finding CMKs and Key Material \(p. 198\)](#)
- [Scheduling Deletion of CMKs from a Custom Key Store \(p. 202\)](#)

## Creating CMKs in a Custom Key Store

After you have created a custom key store, you can create [customer master keys \(p. 2\)](#) (CMKs) in your key store. Then you can use and manage these CMKs very much like you would use any CMK in AWS KMS. For example, you can do any of the following:

- Create aliases that point to the CMKs.
- Set IAM and key policies on the CMKs.
- Enable and disable the CMKs.
- Schedule deletions of the CMKs.

- Use the CMKs for cryptographic operations.

To create a CMK in a custom key store, the custom key store must be [connected to its associated AWS CloudHSM cluster \(p. 186\)](#) and the cluster must contain at least two active HSMs in different Availability Zones. To find the connection status and number of HSMs, view the [custom key stores page \(p. 182\)](#) in the AWS Management Console. When using the API operations, use the [DescribeCustomKeyStores](#) operation to verify that the custom key store is connected. Use the AWS CloudHSM [DescribeClusters](#) operation to get the number of active HSMs in the cluster and their Availability Zones.

When you create a CMK in your custom key store, AWS KMS creates the CMK in AWS KMS. But, it creates the key material for the CMK in the associated AWS CloudHSM cluster. Specifically, AWS KMS signs into the cluster as the [kmsuser CU that you created \(p. 179\)](#). Then it creates a persistent, non-extractable, 256-bit Advanced Encryption Standard (AES) symmetric key in the cluster. AWS KMS sets the value of the [key label attribute](#), which is visible only in the cluster, to Amazon Resource Name (ARN) of the CMK.

When the command succeeds, the [key state \(p. 223\)](#) of the new CMK is `Enabled` and its origin is `AWS_CLOUDHSM`. You cannot change the origin of any CMK after you create it. When you view a CMK in a custom key store in the console or by using the [DescribeKey](#) operation, you can see typical properties, like its key ID, key state, and creation date. But you can also see the custom key store ID and (optionally) the AWS CloudHSM cluster ID. For details, see [Viewing CMKs in a Custom Key Store \(p. 196\)](#).

If your attempt to create a CMK in your custom key store fails, use the error message to help you determine the cause. It might indicate that the custom key store is not connected (`CustomKeyStoreInvalidStateException`) or the associated AWS CloudHSM cluster doesn't have the two active HSMs that are required for this operation (`CloudHsmClusterInvalidConfigurationException`). For help see [Troubleshooting a Custom Key Store \(p. 202\)](#).

#### Topics

- [Create a CMK in a Custom Key Store \(Console\) \(p. 193\)](#)
- [Create a CMK in a Custom Key Store \(API\) \(p. 194\)](#)

## Create a CMK in a Custom Key Store (Console)

Use the following procedure to create a customer master key (CMK) in a custom key store.

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. Choose **Create key**.
5. Choose **Symmetric**.

You cannot create an asymmetric CMK in a custom key store.

#### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

6. Choose **Advanced options**.
7. For **Key material origin**, choose **Custom key store (CloudHSM)**.
8. Choose **Next**.
9. Select a custom key store for your new CMK. To create a new custom key store, choose **Create custom key store**.

The custom key store that you select must have a status of **CONNECTED**. Its associated AWS CloudHSM cluster must be active and contain at least two active HSMs in different Availability Zones.

For help with connecting a custom key store, see [Connecting and Disconnecting a Custom Key Store \(p. 186\)](#). For help with adding HSMs, see [Adding an HSM](#) in the *AWS CloudHSM User Guide*.

10. Choose **Next**.
11. Type an alias and an optional description for the CMK.
12. (Optional). On the **Add Tags** page, add tags that identify or categorize your CMK.

When you add tags to your AWS resources, AWS generates a cost allocation report with usage and costs aggregated by tags. For information about tagging CMKs, see [Tagging Keys \(p. 39\)](#).

13. Choose **Next**.
14. In the **Key Administrators** section, select the IAM users and roles who can manage the CMK. For more information, see [Allows Key Administrators to Administer the CMK \(p. 52\)](#).

**Note**

IAM policies can give other IAM users and roles permission to use the CMK.

15. (Optional) To prevent these key administrators from deleting this CMK, clear the box at the bottom of the page for **Allow key administrators to delete this key**.
16. Choose **Next**.
17. In the **This account** section, select the IAM users and roles in this AWS account who can use the CMK in cryptographic operations. For more information, see [Allows Key Users to Use the CMK \(p. 54\)](#).

**Note**

IAM policies can give other IAM users and roles permission to use the CMK.

18. (Optional) You can allow other AWS accounts to use this CMK for cryptographic operations. To do so, in the **Other AWS accounts** section at the bottom of the page, choose **Add another AWS account** and enter the AWS account identification number of an external account. To add multiple external accounts, repeat this step.

**Note**

Administrators of the other AWS accounts must also allow access to the CMK by creating IAM policies for their users. For more information, see [Allowing Users in Other Accounts to Use a CMK \(p. 71\)](#).

19. Choose **Next**.
20. On the **Review and edit key policy** page, review and edit the policy document for the new CMK. When you're done, choose **Finish**.

When the procedure succeeds, the display shows the new CMK in the custom key store that you chose. When you choose the name or alias of the new CMK, its detail page displays the origin of the CMK (**CloudHSM**), the name and ID of the custom key store, and the ID of the AWS CloudHSM cluster. If the procedure fails, an error message appears that describes the failure.

**Tip**

To make it easier to identify CMKs in a custom key store, on the **Customer managed keys** page, add the **Custom key store ID** column to the display. Click the gear icon in the upper-right and select **Custom key store ID**.

## Create a CMK in a Custom Key Store (API)

To create a new [customer master key \(p. 2\)](#) (CMK) in your custom key store, use the [CreateKey](#) operation. Use the `CustomKeyId` parameter to identify your custom key store and specify an `Origin` value of `AWS_CLOUDHSM`.

```
        "StateMessage": "HSM created.",
        "SubnetId": "subnet-b6b10bd2",
        "HsmId": "hsm-zyxwvutsrq",
        "State": "ACTIVE"
    },
    ],
    "State": "ACTIVE"
}
]
```

This example command uses the [CreateKey](#) operation to create a CMK in the custom key store. To create a CMK in a custom key store, you must provide the ID of the custom key store name and specify an `Origin` value of `AWS_CLOUDHSM`.

The response includes the IDs of the custom key store and the AWS CloudHSM cluster.

Before running this command, replace the example custom key store ID with a valid ID.

```
$ aws kms create-key --origin AWS_CLOUDHSM --custom-key-store-id cks-1234567890abcdef0
{
  "KeyMetadata": {
    "AWSAccountId": "111122223333",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "CreationDate": 1.499288695918E9,
    "Description": "Example key",
    "Enabled": true,
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "KeyManager": "CUSTOMER",
    "KeyState": "Enabled",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "Origin": "AWS_CLOUDHSM",
    "CloudHsmClusterId": "cluster-1a23b4cdefg",
    "CustomKeyStoreId": "cks-1234567890abcdef0",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

## Viewing CMKs in a Custom Key Store

To view the customer master keys (CMKs) in a custom key store, use the same techniques that you would use to view any AWS KMS [customer managed CMKs](#) (p. 2). To learn the basics, see [Viewing Keys](#) (p. 22). To identify the keys in your AWS CloudHSM cluster that serve as key material for your CMK, see [Finding CMKs and Key Material](#) (p. 198).

In the AWS Management Console, the CMKs in your custom key store are displayed along with all other customer managed CMKs your AWS account and Region.

However, the following values are specific to CMKs in a custom key store.

- The name and ID of the custom key store that stores the CMK.
- The cluster ID of the associated AWS CloudHSM cluster that contains their key material.
- An `Origin` value of `CloudHSM` in the AWS Management Console or `AWS_CLOUDHSM` in API responses.
- The [key state](#) (p. 223) value can be `Unavailable`. For help resolving the status, see [How to Fix Unavailable CMKs](#) (p. 203).

### To view the CMKs in a custom key store (Console)

1. Open the AWS KMS console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.
4. In the upper-right corner, choose the gear icon, choose **Custom key store ID** and **Origin**, then choose **Confirm**.
5. To identify CMKs in any custom key store, look for CMKs with an **Origin** value of **AWS\_CLOUDHSM**. To identify CMKs in a particular custom key store, view the values in the **Custom key store ID** column.
6. Choose the alias or key ID of a CMK in a custom key store.

This page displays detailed information about the CMK, including its Amazon Resource Name (ARN), key policy, and tags.

7. Expand **Cryptographic configuration**.

This section includes information about the CMK's custom key store and cluster.

### To view the CMKs in a custom key store (API)

You use the same AWS KMS API operations to view the CMKs in a custom key store that you would use for any CMK, including [ListKeys](#), [DescribeKey](#), and [GetKeyPolicy](#). For example, the following `describe-key` operation in the AWS CLI shows the special fields for a CMK in a custom key store. Before running a command like this one, replace the example CMK ID with a valid value.

```
$ aws kms describe-key --key-id 1234abcd-12ab-34cd-56ef-1234567890ab

{
  "KeyMetadata": {
    "AWSAccountId": "111122223333",
    "KeyId": "1234abcd-12ab-34cd-56ef-1234567890ab",
    "Arn": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "CreationDate": 1537582718.431,
    "Enabled": true,
    "KeyManager": "CUSTOMER",
    "KeyState": "Enabled",
    "KeyUsage": "ENCRYPT_DECRYPT",
    "Origin": "AWS_CLOUDHSM",
    "CloudHsmClusterId": "cluster-1a23b4cdefg",
    "CustomKeyId": "cks-1234567890abcdef0",
    "Description": "CMK in custom key store",
    "CustomerMasterKeySpec": "SYMMETRIC_DEFAULT",
    "EncryptionAlgorithms": [
      "SYMMETRIC_DEFAULT"
    ]
  }
}
```

For help finding the CMKs in a custom key store or identifying the keys in your AWS CloudHSM cluster that serve as key material for your CMK, see [Finding CMKs and Key Material \(p. 198\)](#).

## Using CMKs in a Custom Key Store

After you [create CMKs in a custom key store \(p. 192\)](#), you can use them for cryptographic operations — [Encrypt](#), [Decrypt](#), [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), and [ReEncrypt](#) — just as you would for any CMK. In the request, you identify the CMK by its ID or alias; you do not need to specify the

custom key store or AWS CloudHSM cluster. The response includes the same fields that are returned for any CMK.

However, when you use a CMK in a custom key store, the cryptographic operation is performed entirely within the AWS CloudHSM cluster that is associated with the custom key store. The operation uses the key material in the cluster that is associated with the CMK that you chose.

To make this possible, the following conditions are required.

- The [key state \(p. 223\)](#) of the CMK must be `Enabled`. To find the key state, use the **Status** field in the [AWS Management Console \(p. 196\)](#) or the `KeyState` field in the [DescribeKey](#) response.
- The custom key store must be connected to its AWS CloudHSM cluster. Its **Status** in the [AWS Management Console \(p. 182\)](#) or `ConnectionState` in the [DescribeCustomKeyStores](#) response must be `CONNECTED`.
- The AWS CloudHSM cluster that is associated with the custom key store must contain at least one active HSM. To find the number of active HSMs in the cluster, use the [AWS KMS console \(p. 182\)](#), the AWS CloudHSM console, or the [DescribeClusters](#) operation.
- The AWS CloudHSM cluster must contain the key material for the CMK. If the key material was deleted from the cluster, or an HSM was created from a backup that did not include the key material, the cryptographic operation will fail.

If these conditions are not met, the cryptographic operation fails, and AWS KMS returns a `KMSInvalidStateException` exception. Typically, you just need to [reconnect the custom key store \(p. 186\)](#). For additional help, see [How to Fix a Failing CMK \(p. 203\)](#).

When using the CMKs in a custom key store, be aware that the CMKs in each custom key store share a [per-second quota \(p. 357\)](#) on requests for cryptographic operations. If you exceed the quota, AWS KMS returns a `ThrottlingException`. If the AWS CloudHSM cluster that is associated with the custom key store is processing numerous commands, including those unrelated to the custom key store, you might get a `ThrottlingException` at an even lower rate. If you get a `ThrottlingException` for any request, lower your request rate and try the commands again. For details about the request quota for cryptographic operations in a custom key store, see [Custom Key Store Quotas \(p. 357\)](#).

## Finding CMKs and Key Material

If you manage a custom key store, you might need to identify the CMKs in each custom key store. For example, you might need to do some of the following tasks.

- Track the CMKs in custom key store in AWS CloudTrail logs.
- Predict the effect on CMKs of disconnecting a custom key store.
- Schedule deletion of CMKs before you delete a custom key store.

In addition, you might want to identify the keys in your AWS CloudHSM cluster that serve as key material for your CMKs. Although AWS KMS manages the CMKs and their key material, you still retain control of and responsibility for the management of your AWS CloudHSM cluster, its HSMs and backups and the keys in the HSMs. You might need to identify the keys in order to audit the key material, protect it from accidental deletion, or delete it from HSMs and cluster backups after deleting the CMK.

All key material for the CMKs in your custom key store is owned by the [kmsuser crypto user \(p. 175\)](#) (CU). AWS KMS sets the key label attribute, which is viewable only in AWS CloudHSM, to the Amazon Resource Name (ARN) of the CMK.

To find CMKs and key material, use any of the following techniques.

- [Find the CMKs in a Custom Key Store \(p. 199\)](#) — How to identify the CMKs in one or all of your custom key stores.

- [Find All Keys for a Custom Key Store \(p. 200\)](#) — How to find all keys in your cluster that serve as key material for the CMKs in your custom key store.
- [Find the Key for a CMK \(p. 201\)](#) — How to find the key in your cluster that serves as key material for a particular CMK in your custom key store.
- [Find the CMK for a Key \(p. 200\)](#) — How to find the CMK for a particular key in your cluster.

## Find the CMKs in a Custom Key Store

If you manage a custom key store, you might need to identify the CMKs in each custom key store. You can use this information track the CMK operations in AWS CloudTrail logs, predict the effect on CMKs of disconnecting a custom key store, or schedule deletion of CMKs before you delete a custom key store.

### To find the CMKs in a custom key store (Console)

To find the CMKs in a particular custom key store, on the **Customer Managed Keys** page, view the values in the **Custom Key Store Name** or **Custom Key Store ID** fields. To identify CMKs in any custom key store, look for CMKs with an **Origin** value of **CloudHSM**. To add optional columns to the display, choose the gear icon in the upper right corner of the page.

### To find the CMKs in a custom key store (API)

To find the CMKs in a custom key store, use the [ListKeys](#) and [DescribeKey](#) operations and then filter the `CustomKeyStoreId` value. Before running the examples, replace the fictitious custom key store ID values with a valid value.

Bash

To find CMKs in a particular custom key store, get all of your CMKs in the account and Region. Then filter the ID of the custom key store.

```
for key in $(aws kms list-keys --query 'Keys[*].KeyId' --output text) ;  
do aws kms describe-key --key-id $key |  
grep '"CustomKeyStoreId": "cks-1234567890abcdef0"' --context 100; done
```

To get CMKs in any custom key store in the account and Region, search for `CustomKeyStoreId` values that begin with `cks-`.

```
for key in $(aws kms list-keys --query 'Keys[*].KeyId' --output text) ;  
do aws kms describe-key --key-id $key |  
grep '"CustomKeyStoreId": "cks-" ' --context 100; done
```

PowerShell

To find CMKs in a particular custom key store, use the [Get-KmsKeyList](#) [Get-KmsKey](#) cmdlets to get all of your CMKs in the account and Region. Then filter for the ID of the custom key store.

```
PS C:\> (Get-KMSKeyList).KeyArn | foreach {Get-KMSKey -KeyId $_} | where  
CustomKeyStoreId -eq 'cks-1234567890abcdef0'
```

To get CMKs in any custom key store in the account and Region, use the `-like` comparison operator. All custom key store identifiers begin with `cks-`.

```
PS C:\> (Get-KMSKeyList).KeyArn | foreach {Get-KMSKey -KeyId $_} | where  
CustomKeyStoreId -like 'cks*'
```

## Find All Keys for a Custom Key Store

You can identify the keys in your AWS CloudHSM cluster that serve as key material for your custom key store. To do that, use the [findAllKeys](#) command in `cloudhsm_mgmt_util` to find the key handles of all keys that `kmsuser` owns or shares. Unless you have logged in as `kmsuser` and created keys outside of AWS KMS, all of the keys that `kmsuser` owns represent key material for AWS KMS CMKs.

Any crypto officer in the cluster can run this command without disconnecting the custom key store.

1. Start `cloudhsm_mgmt_util` by using the procedure described in the [Prepare to run cloudhsm\\_mgmt\\_util](#) topic.
2. [Log into cloudhsm\\_mgmt\\_util](#) using a crypto officer (CO) account.
3. Use the [listUsers](#) command to find the user ID of the `kmsuser` crypto user.

In this example, `kmsuser` has user ID 3.

```
aws-cloudhsm> listUsers
Users on server 0(10.0.0.1):
Number of users found:3
```

User Id	User Type	User Name	MofnPubKey	
LoginFailureCnt	2FA			
1	PCO	admin	NO	0
NO				
2	AU	app_user	NO	0
NO				
3	CU	kmsuser	NO	0
NO				

4. Use the [findAllKeys](#) command to find the key handles of all keys that `kmsuser` owns or shares. Replace the example user ID with the actual user ID of `kmsuser` in your cluster.

The example output shows that `kmsuser` owns keys with key handles 8, 9, and 262162 on both HSMs in the cluster.

```
aws-cloudhsm> findAllKeys 3 0
Keys on server 0(10.0.0.1):
Number of keys found 3
number of keys matched from start index 0::6
8,9,262162
findAllKeys success on server 0(10.0.0.1)

Keys on server 1(10.0.0.2):
Number of keys found 6
number of keys matched from start index 0::6
8,9,262162
findAllKeys success on server 1(10.0.0.2)
```

## Find the CMK for a Key

If you know the key handle of a key that `kmsuser` owns in the cluster, you can use the key label to identify the associated CMK in your custom key store.

When AWS KMS creates the key material for a CMK in your AWS CloudHSM cluster, it writes the Amazon Resource Name (ARN) of the CMK in the key label. Unless you have changed the label value, you can use the [getAttribute](#) command in `key_mgmt_util` or `cloudhsm_mgmt_util` to associate the key with its CMK.

To run this procedure, you need to disconnect the custom key store temporarily so you can log in as the `kmsuser` CU.

### Note

While a custom key store is disconnected, all attempts to create customer master keys (CMKs) in the custom key store or to use existing CMKs in cryptographic operations will fail. This action can prevent users from storing and accessing sensitive data.

1. Disconnect the custom key store, if it is not already disconnected., then log into the `key_mgmt_util` as `kmsuser`, as explained in [How to Disconnect and Log In \(p. 208\)](#).
2. Use the `getAttribute` command in `key_mgmt_util` or `cloudhsm_mgmt_util` to get the label attribute (`OBJ_ATTR_LABEL`, attribute 3) for a particular key handle.

For example, this command uses `getAttribute` in `cloudhsm_mgmt_util` to get the label attribute (attribute 3) of the key with key handle 262162. The output shows that key 262162 serves as key material for the CMK with ARN `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`. Before running this command, replace the example key handle with a valid one.

For a list of key attributes, use the `listAttributes` command or see the [Key Attribute Reference](#) in the *AWS CloudHSM User Guide*.

```
aws-cloudhsm> getAttribute 262162 3

Attribute Value on server 0(10.0.1.10):
OBJ_ATTR_LABEL
arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab

Attribute Value on server 1(10.0.1.12):
OBJ_ATTR_EXTRACTABLE
arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

3. Log out of `key_mgmt_util` or `cloudhsm_mgmt_util` and reconnect the custom key store as explained in [How to Log Out and Reconnect \(p. 209\)](#).

## Find the Key for a CMK

You can use the CMK ID of a CMK in a custom key store to identify the key in your cluster that serves as its key material. Then you can use its key handle to identify the key in AWS CloudHSM client commands.

When AWS KMS creates the key material for a CMK in your AWS CloudHSM cluster, it writes the Amazon Resource Name (ARN) of the CMK in the key label. Unless you have changed the label value, you can use the `findKey` command in `key_mgmt_util` to get the key handle of the key material for the CMK. To run this procedure, you need to disconnect the custom key store temporarily so you can log in as the `kmsuser` CU.

### Note

While a custom key store is disconnected, all attempts to create customer master keys (CMKs) in the custom key store or to use existing CMKs in cryptographic operations will fail. This action can prevent users from storing and accessing sensitive data.

1. Disconnect the custom key store, if it is not already disconnected, then log into the `key_mgmt_util` as `kmsuser`, as explained in [How to Disconnect and Log In \(p. 208\)](#).
2. Use the `findKey` command in `key_mgmt_util` to search for a key with a label that matches the ARN of a CMK in your custom key store. Replace the example CMK ARN in the value of the `-l` (lower-case L for 'label') parameter with a valid CMK ARN.

For example, this command finds the key with a label that matches the example CMK ARN, `arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`. The example output shows that the key with key handle 262162 has the specified CMK ARN in its label. You can now use this key handle in other `key_mgmt_util` commands.

```
Command: findKey -l arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab  
Total number of keys present 1  
  
number of keys matched from start index 0::1  
262162  
  
Cluster Error Status  
Node id 1 and err state 0x00000000 : HSM Return: SUCCESS  
Node id 0 and err state 0x00000000 : HSM Return: SUCCESS  
  
Cfm3FindKey returned: 0x00 : HSM Return: SUCCESS
```

3. Log out of key\_mgmt\_util and reconnect the custom key store as explained in [How to Log Out and Reconnect](#) (p. 209).

## Scheduling Deletion of CMKs from a Custom Key Store

When you are certain that you will not need to use a customer master key (CMK) for any cryptographic operation, you can [schedule the deletion of the CMK](#) (p. 160). Use the same procedure that you would use to schedule the deletion of any CMK from AWS KMS. In addition, keep your custom key store connected so AWS KMS can delete the corresponding key material from the associated AWS CloudHSM cluster when the waiting period expires.

### Warning

Deleting a CMK is a destructive and potentially dangerous operation that prevents you from recovering all data encrypted under the CMK. Before scheduling deletion of the CMK, [examine past usage](#) (p. 169) of the CMK and [create a Amazon CloudWatch alarm](#) (p. 165) that alerts you when someone tries to use the CMK while it is pending deletion. Whenever possible, [disable the CMK](#) (p. 41), instead of deleting it.

If you schedule deletion of a CMK from a custom key store, its [key state](#) (p. 223) changes to **Pending deletion**. The CMK remains in the **Pending deletion** state throughout the waiting period, even if the CMK becomes unavailable because you have [disconnected the custom key store](#) (p. 186). This allows you to cancel the deletion of the CMK at any time during the waiting period.

When the waiting period expires, AWS KMS deletes the CMK from AWS KMS. Then AWS KMS makes a best effort to delete the key material from the associated AWS CloudHSM cluster. If AWS KMS cannot delete the key material, such as when the key store is disconnected from AWS KMS, you might need to manually [delete the orphaned key material](#) (p. 206) from the cluster.

AWS KMS does not delete the key material from cluster backups. Even if you delete the CMK from AWS KMS and delete its key material from your AWS CloudHSM cluster, clusters created from backups might contain the deleted key material. To permanently delete the key material [view the creation date](#) (p. 196) of the CMK. Then [delete all cluster backups](#) that might contain the key material.

## Troubleshooting a Custom Key Store

Custom key stores are designed to be available and resilient. However, there are some error conditions that you might have to repair to keep your custom key store operational.

### Topics

- [How to Fix Unavailable CMKs](#) (p. 203)

- [How to Fix a Failing CMK \(p. 203\)](#)
- [How to Fix a Connection Failure \(p. 204\)](#)
- [How to Fix Invalid kmsuser Credentials \(p. 205\)](#)
- [How to Delete Orphaned Key Material \(p. 206\)](#)
- [How to Recover Deleted Key Material for a CMK \(p. 207\)](#)
- [How to Log in as kmsuser \(p. 208\)](#)

## How to Fix Unavailable CMKs

The [key state \(p. 223\)](#) of customer master keys (CMKs) in a custom key store is typically `Enabled`. Like all CMKs, the key state changes when you disable the CMKs in a custom key store or schedule them for deletion. However, unlike other CMKs, the CMKs in a custom key store can also have a [key state \(p. 223\)](#) of `Unavailable`.

A key state of `Unavailable` indicates that the CMK is in a custom key store that was intentionally [disconnected from its AWS CloudHSM cluster \(p. 186\)](#) and attempts to reconnect it, if any, failed. While a CMK is unavailable, you can view and manage the CMK, but you cannot use it for cryptographic operations.

To find the key state of a CMK, on the **Customer managed keys** page, view the **Status** field of the CMK. Or, use the [DescribeKey](#) operation and view the `KeyState` element in the response. For details, see [Viewing Keys \(p. 22\)](#).

The CMKs in a disconnected custom key store will have a key state of `Unavailable` or `PendingDeletion`. CMKs that are scheduled for deletion from a custom key store have a `PendingDeletion` key state, even when the custom key store is disconnected from its AWS CloudHSM cluster. This allows you to cancel the scheduled key deletion without reconnecting the custom key store.

To fix an unavailable CMK, [reconnect the custom key store \(p. 186\)](#). After the custom key store is reconnected, the key state of the CMKs in the custom key store is automatically restored to its previous state, such as `Enabled` or `Disabled`. CMKs that are pending deletion remain in the `PendingDeletion` state. However, while the problem persists, [enabling and disabling an unavailable CMK \(p. 41\)](#) does not change its key state. The enable or disable action takes effect only when the key becomes available.

For help with failed connections, see [How to Fix a Connection Failure \(p. 204\)](#).

## How to Fix a Failing CMK

Problems with creating and using CMKs in custom key stores can be caused by a problem with your custom key store, its associated AWS CloudHSM cluster, the CMK, or its key material.

When a custom key store is disconnected from its AWS CloudHSM cluster, the key state of CMKs in the custom key store is `Unavailable`. All requests to create CMKs in a disconnected custom key store return a `CustomKeyStoreInvalidStateException` exception. All requests to encrypt, decrypt, re-encrypt, or generate data keys return a `KMSInvalidStateException` exception. To fix the problem, [reconnect the custom key store \(p. 186\)](#).

However, your attempts to use a custom key store CMK for cryptographic operations might fail even when its key state is `Enabled` and the connection status of the custom key store is `Connected`. This might be caused by any of the following conditions.

- The key material for the CMK might have been deleted from the associated AWS CloudHSM cluster. To investigate, [find the key handle \(p. 196\)](#) of the key material for a CMK and, if necessary, try to [recover the key material \(p. 207\)](#).

- All HSMs were deleted from the AWS CloudHSM cluster that is associated with the custom key store. To use a CMK in a custom key store in a cryptographic operation, its AWS CloudHSM cluster must contain at least one active HSM. To verify the number and state of HSMs in an AWS CloudHSM cluster, [use the AWS CloudHSM console](#) or the [DescribeClusters](#) operation. To add an HSM to the cluster, use the AWS CloudHSM console or the [CreateHsm](#) operation.
- The AWS CloudHSM cluster associated with the custom key store was deleted. To fix the problem, [create a cluster from a backup](#) that is related to the original cluster, such as a backup of the original cluster, or a backup that was used to create the original cluster. Then, [edit the cluster ID \(p. 184\)](#) in the custom key store settings. For instructions, see [How to Recover Deleted Key Material for a CMK \(p. 207\)](#).

## How to Fix a Connection Failure

If you try to [connect a custom key store \(p. 186\)](#) to its AWS CloudHSM cluster, but the operation fails, the connection status of the custom key store changes to `FAILED`. To find the status of a custom key store, view the **Status** column of the custom key store in the AWS Management Console or the `ConnectionState` element in the [DescribeCustomKeyStores](#) response.

Alternatively, some connection attempts fail quickly due to easily detected cluster configuration errors. In this case, the **Status** or `ConnectionState` is still `DISCONNECTED`. These failures return an error message or [exception](#) that explains why the attempt failed. Review the exception description and [cluster requirements \(p. 179\)](#), fix the problem, [update the custom key store \(p. 184\)](#), if necessary, and try to connect again.

When the connection status is `FAILED`, run the [DescribeCustomKeyStores](#) operation and see the `ConnectionErrorCode` element in the response.

### Note

When the connection status of a custom key store is `FAILED`, you must [disconnect the custom key store \(p. 186\)](#) before attempting to reconnect it. You cannot connect a custom key store with a `FAILED` connection status.

- `CLUSTER_NOT_FOUND` indicates that AWS KMS cannot find an AWS CloudHSM cluster with the specified cluster ID. This might occur because the wrong cluster ID was provided to an API operation or the cluster was deleted and not replaced. To fix this error, verify the cluster ID, such as by using the AWS CloudHSM console or the [DescribeClusters](#) operation. If the cluster was deleted, [create a cluster from a recent backup](#) of the original. Then, [disconnect the custom key store \(p. 186\)](#), [edit the custom key store \(p. 184\)](#) cluster ID setting, and [reconnect the custom key store \(p. 186\)](#) to the cluster.
- `INSUFFICIENT_CLOUDHSM_HSMS` indicates that the associated AWS CloudHSM cluster does not contain any HSMs. To connect, the cluster must have at least one HSM. To find the number of HSMs in the cluster, use the [DescribeClusters](#) operation. To resolve this error, [add at least one HSM](#) to the cluster. If you add multiple HSMs, it's best to create them in different Availability Zones.
- `INTERNAL_ERROR` indicates that AWS KMS could not complete the request due to an internal error. Retry the request. For `ConnectCustomKeyStore` requests, disconnect the custom key store before trying to connect again.
- `INVALID_CREDENTIALS` indicates that AWS KMS cannot log into the associated AWS CloudHSM cluster because it doesn't have the correct `kmsuser` account password. For help with this error, see [How to Fix Invalid `kmsuser` Credentials \(p. 205\)](#).

- `NETWORK_ERRORS` usually indicates transient network issues. [Disconnect the custom key store \(p. 186\)](#), wait a few minutes, and try to connect again.
- `USER_LOCKED_OUT` indicates that the [kmsuser crypto user \(CU\) account \(p. 175\)](#) is locked out of the associated AWS CloudHSM cluster due to too many failed password attempts. For help with this error, see [How to Fix Invalid kmsuser Credentials \(p. 205\)](#).

To fix this error, [disconnect the custom key store \(p. 186\)](#) and use the `changePswd` command in `cloudhsm_mgmt_util` to change the `kmsuser` account password. Then, [edit the kmsuser password setting \(p. 184\)](#) for the custom key store, and try to connect again. For help, use the procedure described in the [How to Fix Invalid kmsuser Credentials \(p. 205\)](#) topic.

- `USER_LOGGED_IN` indicates that the `kmsuser` CU account is logged into the associated AWS CloudHSM cluster. This prevents AWS KMS from rotating the `kmsuser` account password and logging into the cluster. To fix this error, log the `kmsuser` CU out of the cluster. If you changed the `kmsuser` password to log into the cluster, you must also update the key store password value for the custom key store. For help, see [How to Log Out and Reconnect \(p. 209\)](#).
- `USER_NOT_FOUND` indicates that AWS KMS cannot find a `kmsuser` CU account in the associated AWS CloudHSM cluster. To fix this error, [create a kmsuser CU account \(p. 180\)](#) in the cluster, and then [update the key store password value \(p. 184\)](#) for the custom key store. For help, see [How to Fix Invalid kmsuser Credentials \(p. 205\)](#).

## How to Fix Invalid kmsuser Credentials

When you [connect a custom key store \(p. 186\)](#), AWS KMS logs into the associated AWS CloudHSM cluster as the [kmsuser crypto user \(p. 175\)](#) (CU). It remains logged in until the custom key store is disconnected. The `DescribeCustomKeyStores` response shows a `ConnectionState` of `FAILED` and `ConnectionErrorCode` value of `INVALID_CREDENTIALS`, as shown in the following example.

If you disconnect the custom key store and change the `kmsuser` password, AWS KMS cannot log into the AWS CloudHSM cluster with the credentials of the `kmsuser` CU account. As a result, all attempts to connect the custom key store fail. The `DescribeCustomKeyStores` response shows a `ConnectionState` of `FAILED` and `ConnectionErrorCode` value of `INVALID_CREDENTIALS`, as shown in the following example.

```
$ aws kms describe-custom-key-stores --custom-key-store-name ExampleKeyStore
{
  "CustomKeyStores": [
    {
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "ConnectionErrorCode": "INVALID_CREDENTIALS",
      "CustomKeyId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "TrustAnchorCertificate": "<certificate string appears here>",
      "CreationDate": "1.499288695918E9",
      "ConnectionState": "FAILED"
    }
  ],
}
```

Also, after five failed attempts to log into the cluster with an incorrect password, AWS CloudHSM locks the user account. To log into the cluster, you must change the account password.

If AWS KMS gets a lockout response when it tries to log into the cluster as the `kmsuser` CU, the request to connect the custom key store fails. The [DescribeCustomKeyStores](#) response includes a `ConnectionState` of `FAILED` and `ConnectionErrorCode` value of `USER_LOCKED_OUT`, as shown in the following example.

```
$ aws kms describe-custom-key-stores --custom-key-store-name ExampleKeyStore
{
  "CustomKeyStores": [
    {
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "ConnectionErrorCode": "USER_LOCKED_OUT",
      "CustomKeyStoreId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "TrustAnchorCertificate": "<certificate string appears here>",
      "CreationDate": "1.499288695918E9",
      "ConnectionState": "FAILED"
    }
  ],
}
```

To repair any of these conditions, use the following procedure.

1. [Disconnect the custom key store \(p. 186\)](#).
2. Run the [DescribeCustomKeyStores](#) operation and view the value of the `ConnectionErrorCode` element in the response.
  - If the `ConnectionErrorCode` value is `INVALID_CREDENTIALS`, determine the current password for the `kmsuser` account. If necessary, use the [changePswd](#) command in `cloudhsm_mgmt_util` to set the password to a known value.
  - If the `ConnectionErrorCode` value is `USER_LOCKED_OUT`, you must use the [changePswd](#) command in `cloudhsm_mgmt_util` to change the `kmsuser` password.
3. [Edit the kmsuser password setting \(p. 184\)](#) so it matches the current `kmsuser` password in the cluster. This action tells AWS KMS which password to use to log into the cluster. It does not change the `kmsuser` password in the cluster.
4. [Connect the custom key store \(p. 186\)](#).

## How to Delete Orphaned Key Material

After scheduling deletion of a CMK from a custom key store, you might need to manually delete the corresponding key material from the associated cluster.

When you create a CMK in a custom key store, AWS KMS creates the CMK metadata in AWS KMS and generates the key material in the associated AWS CloudHSM cluster. When you schedule deletion of a CMK in a custom key store, after the waiting period, AWS KMS deletes the CMK metadata. Then AWS KMS makes a best effort to delete the corresponding key material from the cluster. AWS KMS does not attempt to delete key material from cluster backups.

If AWS KMS cannot delete the key material, such as when the custom key store is disconnected, AWS KMS writes an entry to your AWS CloudTrail logs. The entry includes the CMK ID, the AWS CloudHSM cluster ID, and the key handle of the key material.

To delete the key material from the associated AWS CloudHSM cluster, use a procedure like the following one. This example uses the AWS CLI and AWS CloudHSM command line tools, but you can use the AWS Management Console instead of the CLI.

1. Disconnect the custom key store, if it is not already disconnected, then log into the `key_mgmt_util`, as explained in [How to Disconnect and Log In \(p. 208\)](#).
2. Use the [deleteKey](#) command in `key_mgmt_util` to delete the key from the HSMs in the cluster.

For example, this command deletes key 262162 from the HSMs in the cluster. The key handle is listed in the CloudTrail log entry.

```
Command: deleteKey -k 262162

Cfm3DeleteKey returned: 0x00 : HSM Return: SUCCESS

Cluster Error Status
Node id 0 and err state 0x00000000 : HSM Return: SUCCESS
Node id 1 and err state 0x00000000 : HSM Return: SUCCESS
Node id 2 and err state 0x00000000 : HSM Return: SUCCESS
```

3. Log out of `key_mgmt_util` and reconnect the custom key store as described in [How to Log Out and Reconnect](#) (p. 209).

## How to Recover Deleted Key Material for a CMK

If the key material for a customer master key is deleted, the CMK is unusable and all ciphertext that was encrypted under the CMK cannot be decrypted. This can happen if the key material for a CMK in a custom key store is deleted from the associated AWS CloudHSM cluster. However, it might be possible to recover the key material.

When you create a customer master key (CMK) in a custom key store, AWS KMS logs into the associated AWS CloudHSM cluster and creates the key material for the CMK. It also changes the password to a value that only it knows and remains logged in as long as the custom key store is connected. Because only the key owner, that is, the CU who created a key, can delete the key, it is unlikely that the key will be deleted from the HSMs accidentally.

However, if the key material for a CMK is deleted from the HSMs in a cluster, the CMK key state eventually changes to `UNAVAILABLE`. If you attempt to use the CMK for a cryptographic operation, the operation fails with a `KMSInvalidStateException` exception. Most importantly, any data that was encrypted under the CMK cannot be decrypted.

Under certain circumstances, you can recover deleted key material by [creating a cluster from a backup](#) that contains the key material. This strategy works only when at least one backup was created while the key existed and before it was deleted.

Use the following process to recover the key material.

1. Find a cluster backup that contains the key material. The backup must also contain all users and keys that you need to support the cluster and its encrypted data.

Use the [DescribeBackups](#) operation to list the backups for a cluster. Then use the backup timestamp to help you select a backup. To limit the output to the cluster that is associated with the custom key store, use the `Filters` parameter, as shown in the following example.

```
$ aws cloudhsmv2 describe-backups --filters clusterIds=<cluster ID>
{
  "Backups": [
    {
      "ClusterId": "cluster-1a23b4cdefg",
      "BackupId": "backup-9g87f6edcba",
      "CreateTimestamp": 1536667238.328,
      "BackupState": "READY"
    },
    ...
  ]
}
```

2. [Create a cluster from the selected backup](#). Verify that the backup contains the deleted key and other users and keys that the cluster requires.
3. [Disconnect the custom key store \(p. 186\)](#) so you can edit its properties.
4. [Edit the cluster ID \(p. 184\)](#) of the custom key store. Enter the cluster ID of the cluster that you created from the backup. Because the cluster shares a backup history with the original cluster, the new cluster ID should be valid.
5. [Reconnect the custom key store \(p. 186\)](#).

## How to Log in as `kmsuser`

To create and manage the key material in the AWS CloudHSM cluster for your custom key store, AWS KMS uses the [`kmsuser` crypto user \(CU\) account \(p. 175\)](#). You [create the `kmsuser` CU account \(p. 179\)](#) in your cluster and provide its password to AWS KMS when you create your custom key store.

In general, AWS KMS manages the `kmsuser` account. However, for some tasks, you need to disconnect the custom key store, log into the cluster as the `kmsuser` CU, and use the `cloudhsm_mgmt_util` and `key_mgmt_util` command line tools.

### Note

While a custom key store is disconnected, all attempts to create customer master keys (CMKs) in the custom key store or to use existing CMKs in cryptographic operations will fail. This action can prevent users from storing and accessing sensitive data.

This topic explains how to [disconnect your custom key store and log in \(p. 208\)](#) as `kmsuser`, run the AWS CloudHSM command line tool, and [log out and reconnect your custom key store \(p. 209\)](#).

### Topics

- [How to Disconnect and Log In \(p. 208\)](#)
- [How to Log Out and Reconnect \(p. 209\)](#)

## How to Disconnect and Log In

Use the following procedure each time to need to log into an associated cluster as the `kmsuser` CU.

1. Disconnect the custom key store, if it is not already disconnected. You can use the AWS Management Console or AWS KMS API.

While your custom key is connected, AWS KMS is logged in as the `kmsuser`. This prevents you from logging in as `kmsuser` or changing the `kmsuser` password.

For example, this command uses [DisconnectCustomKeyStore](#) to disconnect an example key store. Replace the example custom key store ID with a valid one.

```
$ aws kms disconnect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

2. Start `cloudhsm_mgmt_util`. Use the procedure described in [Prepare to run `cloudhsm\_mgmt\_util`](#) section of the *AWS CloudHSM User Guide*.
3. Log into `cloudhsm_mgmt_util` on the AWS CloudHSM cluster as a [crypto officer \(CO\)](#).

For example, this command logs in as a CO named `admin`. Replace the example CO user name and password with valid values.

```
aws-cloudhsm>loginHSM CO admin <password>
```

```
loginHSM success on server 0(10.0.2.9)
loginHSM success on server 1(10.0.3.11)
loginHSM success on server 2(10.0.1.12)
```

4. Use the [changePswd](#) command to change the password of the kmsuser account to one that you know. (AWS KMS rotates the password when you connect your custom key store.) The password must consist of 7-32 alphanumeric characters. It is case-sensitive and cannot contain any special characters.

For example, this command changes the kmsuser password to tempPassword.

```
aws-cloudhsm>changePswd CU kmsuser tempPassword

*****CAUTION*****
This is a CRITICAL operation, should be done on all nodes in the
cluster. Cav server does NOT synchronize these changes with the
nodes on which this operation is not executed or failed, please
ensure this operation is executed on all nodes in the cluster.
*****

Do you want to continue(y/n)?y
Changing password for kmsuser(CU) on 3 nodes
```

5. Log into key\_mgmt\_util or cloudhsm\_mgmt\_util as kmsuser using the password that you set. For detailed instructions, see [Getting Started with cloudhsm\\_mgmt\\_util](#) and [Getting Started with key\\_mgmt\\_util](#). The tool that you use depends on your task.

For example, this command logs into key\_mgmt\_util.

```
Command: loginHSM -u CU -s kmsuser -p tempPassword
Cfm3LoginHSM returned: 0x00 : HSM Return: SUCCESS

Cluster Error Status
Node id 0 and err state 0x00000000 : HSM Return: SUCCESS
Node id 1 and err state 0x00000000 : HSM Return: SUCCESS
Node id 2 and err state 0x00000000 : HSM Return: SUCCESS
```

## How to Log Out and Reconnect

1. Perform the task, then log out of the command line tool. If you do not log out, attempts to reconnect your custom key store will fail.

```
Command: logoutHSM
Cfm3LogoutHSM returned: 0x00 : HSM Return: SUCCESS

Cluster Error Status
Node id 0 and err state 0x00000000 : HSM Return: SUCCESS
Node id 1 and err state 0x00000000 : HSM Return: SUCCESS
```

2. [Edit the kmsuser password setting \(p. 184\)](#) for the custom key store.

This tells AWS KMS the current password for kmsuser in the cluster. If you omit this step, AWS KMS will not be able to log into the cluster as kmsuser, and all attempts to reconnect your custom key store will fail. You can use the AWS Management Console or the KeyStorePassword parameter of the [UpdateCustomKeyStore](#) operation.

For example, this command tells AWS KMS that the current password is tempPassword. Replace the example password with the actual one.

```
$ aws kms update-custom-key-store --custom-key-store-id cks-1234567890abcdef0 --key-store-password tempPassword
```

3. Reconnect the custom key store to AWS KMS. Replace the example custom key store ID with a valid one. During the connection process, AWS KMS changes the kmsuser password to a value that only it knows.

The [ConnectCustomKeyStore](#) operation returns quickly, but the connection process can take an extended period of time. The initial response does not indicate the success of the connection process.

```
$ aws kms connect-custom-key-store --custom-key-store-id cks-1234567890abcdef0
```

4. Use the [DescribeCustomKeyStores](#) operation to verify that the custom key store is connected. Replace the example custom key store ID with a valid one.

In this example, the connection state field shows that the custom key store is now connected.

```
$ aws kms describe-custom-key-stores --custom-key-store-id cks-1234567890abcdef0
{
  "CustomKeyStores": [
    {
      "CustomKeyStoreId": "cks-1234567890abcdef0",
      "CustomKeyStoreName": "ExampleKeyStore",
      "CloudHsmClusterId": "cluster-1a23b4cdefg",
      "TrustAnchorCertificate": "<certificate string appears here>",
      "CreationDate": "1.499288695918E9",
      "ConnectionState": "CONNECTED"
    }
  ],
}
```

# Connecting to AWS KMS Through a VPC Endpoint

You can connect directly to AWS KMS through a private endpoint in your VPC instead of connecting over the internet. When you use a VPC endpoint, communication between your VPC and AWS KMS is conducted entirely within the AWS network.

AWS KMS supports [Amazon Virtual Private Cloud](#) (Amazon VPC) [interface endpoints](#) that are powered by [AWS PrivateLink](#). Each VPC endpoint is represented by one or more [Elastic Network Interfaces](#) (ENIs) with private IP addresses in your VPC subnets.

The VPC interface endpoint connects your VPC directly to AWS KMS without an internet gateway, NAT device, VPN connection, or AWS Direct Connect connection. The instances in your VPC do not need public IP addresses to communicate with AWS KMS.

You can specify the VPC endpoint in [AWS KMS API operations](#) and [AWS CLI commands](#). For example, the following command uses the **endpoint-url** parameter to specify a VPC endpoint in an AWS CLI command to AWS KMS.

```
$ aws kms list-keys --endpoint-url https://vpce-0295a3caf8414c94a-dfm9tr04.kms.us-east-1.vpce.amazonaws.com
```

If you use the default domain name servers (**AmazonProvidedDNS**) and enable [private DNS hostnames](#) for your VPC endpoint, you do not need to specify the endpoint URL. AWS populates your VPC name server with private zone data, so the public KMS endpoint (`https://kms.<region>.amazonaws.com`) resolves to your private VPC endpoint. To enable this feature when using your own name servers, forward requests for the KMS domain to the VPC name server.

You can also use AWS CloudTrail logs to audit your use of KMS keys through the VPC endpoint. And you can use the conditions in IAM and key policies to deny access to any request that does not come from a specified VPC or VPC endpoint.

## Note

Use caution when creating IAM and key policies based on your VPC endpoint. If a policy statement requires that requests come from a particular VPC or VPC endpoint, requests from integrated AWS services that use the CMK on your behalf might fail. For help, see [Using VPC Endpoint Conditions in Policies with AWS KMS Permissions](#) (p. 87).

## Supported AWS Regions

AWS KMS supports VPC endpoints in all AWS Regions where both [Amazon VPC](#) and [AWS KMS](#) are available.

## Topics

- [Create an AWS KMS VPC Endpoint](#) (p. 212)
- [Connecting to an AWS KMS VPC Endpoint](#) (p. 214)
- [Using a VPC Endpoint in a Policy Statement](#) (p. 215)
- [Audit the CMK Use for your VPC](#) (p. 217)

## Create an AWS KMS VPC Endpoint

You [create an interface endpoint](#) in your VPC by using the KMS VPC endpoint service in each region. You can create a VPC endpoint in the AWS Management Console, or by using the [AWS CLI](#) or [Amazon EC2 API](#).

### Topics

- [Creating an AWS KMS VPC Endpoint \(VPC Console\)](#) (p. 212)
- [Creating an AWS KMS VPC Endpoint \(AWS CLI\)](#) (p. 213)

## Creating an AWS KMS VPC Endpoint (VPC Console)

1. Sign in to the AWS Management Console and open the Amazon VPC console at <https://console.aws.amazon.com/vpc/>.
2. On the navigation bar, use the region selector to choose your region.
3. In the navigation pane, choose **Endpoints**. In the main pane, **Create Endpoint**.
4. For **Service category**, choose **AWS services**.
5. In the **Service Name** list, choose the entry for AWS KMS interface endpoint in the region. For example, in the US East (N.Virginia) Region, the entry name is `com.amazonaws.us-east-1.kms`.
6. For **VPC**, select a VPC. The endpoint is created in the VPC that you select.
7. For **Subnets**, choose a subnet from each Availability Zone that you want to include.

The VPC endpoint can span multiple Availability Zones. An elastic network interface (ENI) for the VPC endpoint is created in each subnet that you choose. Each ENI has a DNS hostname and a private IP address.

8. In this step, you can enable a private DNS hostname for your VPC endpoint. If you select the **Enable Private DNS Name** option, the standard AWS KMS DNS hostname (`https://kms.<region>.amazonaws.com`) resolves to your VPC endpoint.

This option makes it easier to use the VPC endpoint. The AWS KMS CLI and SDKs use the standard AWS KMS DNS hostname by default, so you do not need to specify the VPC endpoint URL in applications and commands.

This feature works only when the `enableDnsHostnames` and `enableDnsSupport` attributes of your VPC are set to `true`. To set these attributes, [update DNS support for your VPC](#).

To enable a private DNS hostname, for **Enable Private DNS Name**, select **Enable for this endpoint**.

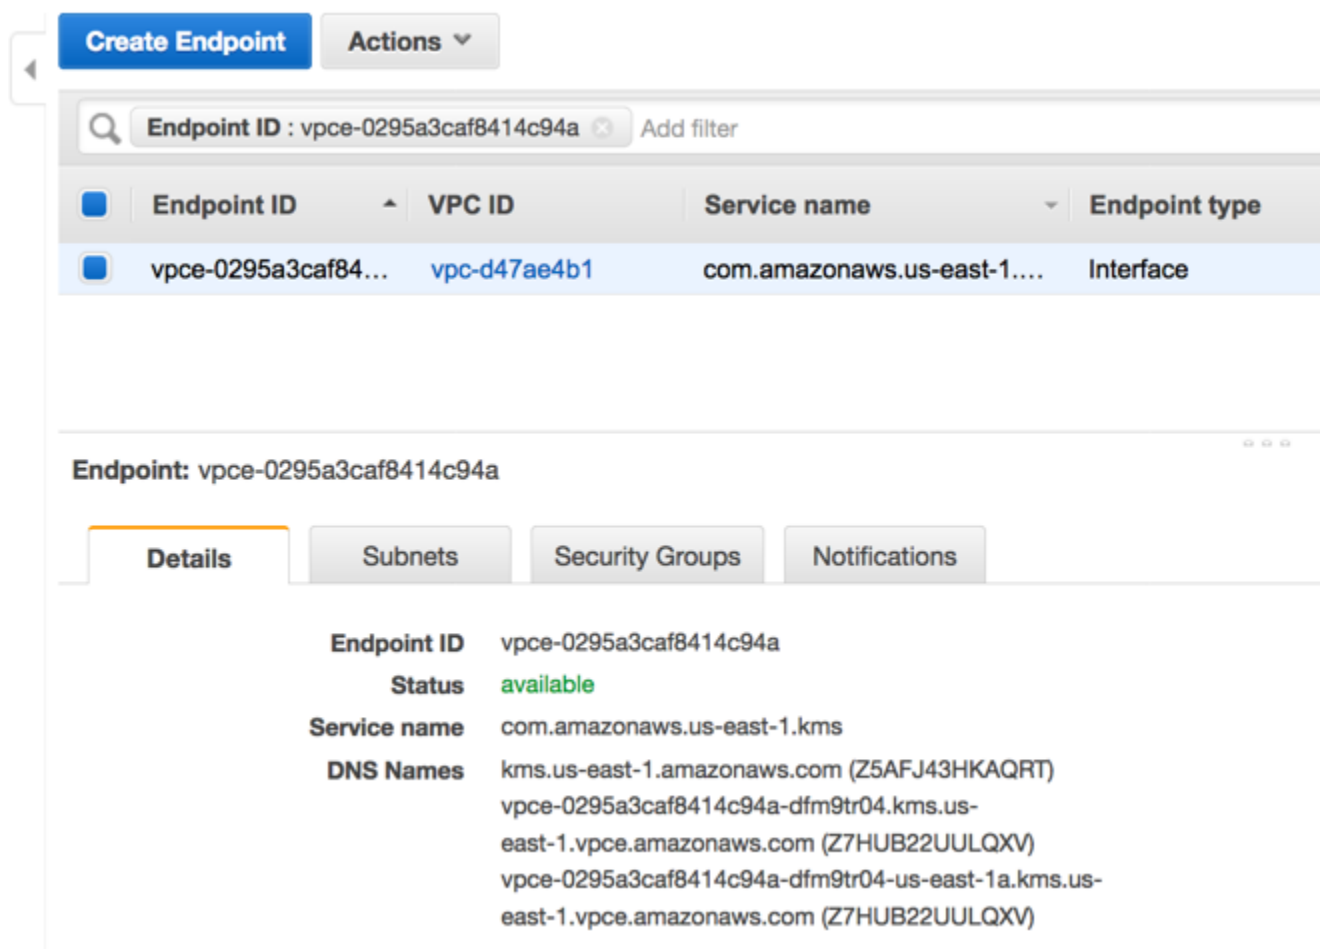

9. For **Security group**, select or create a security group.

You can use [security groups](#) to control access to your endpoint, much like you would use a firewall.

10. Choose **Create endpoint**.

The results show the VPC endpoint, including the VPC endpoint ID and the DNS names that you use to [connect to your VPC endpoint](#) (p. 214).

You can also use the Amazon VPC tools to view and manage your endpoint, including creating a notification for an endpoint, changing properties of the endpoint, and deleting the endpoint. For instructions, see [Interface VPC Endpoints](#).

## Creating an AWS KMS VPC Endpoint (AWS CLI)

You can use the `create-vpc-endpoint` command in the AWS CLI to create a VPC endpoint that connects to AWS KMS.

Be sure to use `interface` as the VPC endpoint type and a service name value that includes `kms` and the region where your VPC is located.

The command does not include the `PrivateDnsNames` parameter because its default value is `true`. To disable this option, you can include the parameter with a value of `false`. Private DNS names are available only when the `enableDnsHostnames` and `enableDnsSupport` attributes of your VPC are set to `true`. To set these attributes, use the [ModifyVpcAttribute](#) operation.

The following diagram shows the syntax of the command.

```
aws ec2 create-vpc-endpoint --vpc-id <vpc id> \
  --vpc-endpoint-type Interface \
  --service-name com.amazonaws.<region>.kms \
  --subnet-ids <subnet id> \
  --security-group-id <security group id>
```

For example, this command creates a VPC endpoint in the VPC with VPC ID `vpce-1a2b3c4d`, which is in the `us-east-1` region. It specifies just one subnet ID to represent the Availability Zones, but you can specify many. The security group ID is also required.

The output includes the VPC endpoint ID and DNS names that you use to connect to your new VPC endpoint.

```
$ aws ec2 create-vpc-endpoint --vpc-id vpc-1a2b3c4d \
                             --vpc-endpoint-type Interface \
                             --service-name com.amazonaws.us-west-1.kms \
                             --subnet-ids subnet-a6b10bd1 \
                             --security-group-id sg-1a2b3c4d

{
  "VpcEndpoint": {
    "PolicyDocument": "{\n  \"Statement\": [\n    {\n      \"Action\": \"*\", \n\n\n    }\n  ]\n  \"Effect\": \"Allow\", \n\n  \"Principal\": \"*\", \n\n  \"Resource\": \"*\"\n}\n",
    "VpcId": "vpc-1a2b3c4d",
    "NetworkInterfaceIds": [
      "eni-bf8aa46b"
    ],
    "SubnetIds": [
      "subnet-a6b10bd1"
    ],
    "PrivateDnsEnabled": true,
    "State": "pending",
    "ServiceName": "com.amazonaws.us-east-1.kms",
    "RouteTableIds": [],
    "Groups": [
      {
        "GroupName": "default",
        "GroupId": "sg-1a2b3c4d"
      }
    ],
    "VpcEndpointId": "vpce-0295a3caf8414c94a",
    "VpcEndpointType": "Interface",
    "CreationTimestamp": "2017-09-05T20:14:41.240Z",
    "DnsEntries": [
      {
        "HostedZoneId": "Z7HUB22UULQXV",
        "DnsName": "vpce-0295a3caf8414c94a-dfm9tr04.kms.us-east-1.vpce.amazonaws.com"
      },
      {
        "HostedZoneId": "Z7HUB22UULQXV",
        "DnsName": "vpce-0295a3caf8414c94a-dfm9tr04-us-east-1a.kms.us-east-1.vpce.amazonaws.com"
      },
      {
        "HostedZoneId": "Z1K56Z6FNPJRR",
        "DnsName": "kms.us-east-1.amazonaws.com"
      }
    ]
  }
}
```

## Connecting to an AWS KMS VPC Endpoint

You can connect to AWS KMS through the VPC endpoint by using the AWS CLI or an AWS SDK. To specify the VPC endpoint, use its DNS name.

For example, this [list-keys](#) command uses the `endpoint-url` parameter to specify the VPC endpoint. To use a command like this, replace the example VPC endpoint ID with one in your account.

```
aws kms list-keys --endpoint-url https://vpce-0295a3caf8414c94a-dfm9tr04.kms.us-east-1.vpce.amazonaws.com
```

If you enabled private hostnames when you created your VPC endpoint, you do not need to specify the VPC endpoint URL in your CLI commands or application configuration. The standard AWS KMS DNS hostname (<https://kms.<region>.amazonaws.com>) resolves to your VPC endpoint. The AWS CLI and SDKs use this hostname by default, so you can begin using the VPC endpoint without changing anything in your scripts and application.

To use private hostnames, the `enableDnsHostnames` and `enableDnsSupport` attributes of your VPC must be set to true. To set these attributes, use the [ModifyVpcAttribute](#) operation.

## Using a VPC Endpoint in a Policy Statement

You can use IAM policies and AWS KMS key policies to control access to your AWS KMS customer master keys (CMKs). You can also use [global condition keys](#) to restrict these policies based on VPC endpoint or VPC in the request.

- Use the `aws:sourceVpce` condition key to grant or restrict access to an AWS KMS CMK based on the VPC endpoint.
- Use the `aws:sourceVpc` condition key to grant or restrict access to an AWS KMS CMK based on the VPC that hosts the private endpoint.

### Note

Use caution when creating IAM and key policies based on your VPC endpoint. If a policy statement requires that requests come from a particular VPC or VPC endpoint, requests from integrated AWS services that use the CMK on your behalf might fail. For help, see [Using VPC Endpoint Conditions in Policies with AWS KMS Permissions \(p. 87\)](#).

Also, the `aws:sourceIP` condition key is not effective when the request comes from an [Amazon VPC endpoint](#). To restrict requests to a VPC endpoint, use the `aws:sourceVpce` or `aws:sourceVpc` condition keys. For more information, see [VPC Endpoints - Controlling the Use of Endpoints](#) in the *Amazon VPC User Guide*.

For example, the following sample key policy allows a user to perform encryption operations with a CMK only when the request comes through the specified VPC endpoint.

When a user makes a request to AWS KMS, the VPC endpoint ID in the request is compared to the `aws:sourceVpce` condition key value in the policy. If they do not match, then the request is denied.

To use a policy like this one, replace the placeholder AWS account ID and VPC endpoint IDs with valid values for your account.

```
{
  "Id": "example-key-1",
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "Enable IAM user permissions",
      "Effect": "Allow",
      "Principal": {"AWS":["111122223333"]},
      "Action": ["kms:*"],
      "Resource": "*"
    },
    {
      "Sid": "Restrict usage to my VPC endpoint",
      "Effect": "Deny",
```

```

        "Principal": "*",
        "Action": [
            "kms:Encrypt",
            "kms:Decrypt",
            "kms:ReEncrypt*",
            "kms:GenerateDataKey*"
        ],
        "Resource": "*",
        "Condition": {
            "StringNotEquals": {
                "aws:sourceVpc": "vpce-0295a3caf8414c94a"
            }
        }
    }
}
]
}

```

You can also use the `aws:sourceVpc` condition key to restrict access to your CMKs based on the VPC in which VPC endpoint resides.

The following sample key policy allows commands that manage the CMK only when they come from `vpc-12345678`. In addition, it allows commands that use the CMK for cryptographic operations only when they come from `vpc-2b2b2b2b`. You might use a policy like this one if an application is running in one VPC, but you use a second, isolated VPC for management functions.

To use a policy like this one, replace the placeholder AWS account ID and VPC endpoint IDs with valid values for your account.

```

{
    "Id": "example-key-2",
    "Version": "2012-10-17",
    "Statement": [
        {
            "Sid": "Allow administrative actions from vpc-12345678",
            "Effect": "Allow",
            "Principal": {"AWS": "111122223333"},
            "Action": [
                "kms:Create*", "kms:Enable*", "kms:Put*", "kms:Update*",
                "kms:Revoke*", "kms:Disable*", "kms:Delete*",
                "kms:TagResource", "kms:UntagResource"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:sourceVpc": "vpc-12345678"
                }
            }
        },
        {
            "Sid": "Allow key usage from vpc-2b2b2b2b",
            "Effect": "Allow",
            "Principal": {"AWS": "111122223333"},
            "Action": [
                "kms:Encrypt", "kms:Decrypt", "kms:GenerateDataKey*"
            ],
            "Resource": "*",
            "Condition": {
                "StringEquals": {
                    "aws:sourceVpc": "vpc-2b2b2b2b"
                }
            }
        }
    ]
}

```

```
        "Sid": "Allow read actions from everywhere",
        "Effect": "Allow",
        "Principal": {"AWS": "111122223333"},
        "Action": [
            "kms:Describe*", "kms:List*", "kms:Get*"
        ],
        "Resource": "*",
    }
}
```

## Audit the CMK Use for your VPC

When a request to AWS KMS uses a VPC endpoint, the VPC endpoint ID appears in the [AWS CloudTrail log \(p. 293\)](#) entry that records the request. You can use the endpoint ID to audit the use of your AWS KMS VPC endpoint.

For example, this sample log entry records a `GenerateDataKey` request that used the VPC endpoint. The `vpcEndpointId` field appears at the end of the log entry.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "EX_PRINCIPAL_ID",
    "arn": "arn:aws:iam::111122223333:user/Alice",
    "accessKeyId": "EXAMPLE_KEY_ID",
    "accountId": "111122223333",
    "userName": "Alice"
  },
  "eventTime": "2018-01-16T05:46:57Z",

```

# Using Hybrid Post-Quantum TLS with AWS KMS

AWS Key Management Service (AWS KMS) now supports a hybrid post-quantum key exchange option for the Transport Layer Security (TLS) network encryption protocol. You can use this TLS option when you connect to KMS API endpoints. We're offering this feature before post-quantum algorithms are standardized so you can begin testing the effect of these key exchange protocols on AWS KMS calls. These optional hybrid post-quantum key exchange features are at least as secure as the TLS encryption we use today and are likely to provide additional security benefits. However, they affect latency and throughput compared to the classic key exchange protocols in use today.

The data that you send to AWS Key Management Service (AWS KMS) is protected in transit by the encryption provided by a Transport Layer Security (TLS) connection. The classic cipher suites that AWS KMS supports for TLS sessions make brute force attacks on the key exchange mechanisms infeasible with current technology. However, if large-scale quantum computing becomes practical in the future, the classic cipher suites used in TLS key exchange mechanisms will be susceptible to these attacks. If you're developing applications that rely on the long-term confidentiality of data passed over a TLS connection, you should consider a plan to migrate to post-quantum cryptography before large-scale quantum computers become available for use. AWS is working to prepare for this future, and we want you to be well-prepared, too.

To protect data encrypted today against potential future attacks, AWS is participating with the cryptographic community in the development of quantum-resistant or *post-quantum* algorithms. We've implemented hybrid post-quantum key exchange cipher suites in AWS KMS endpoints. These hybrid cipher suites, which combine classic and post-quantum elements, ensure that your TLS connection is at least as strong as it would be with classic cipher suites.

These hybrid cipher suites are available for use on your production workloads in [most AWS Regions](#) (p. 218). However, because the performance characteristics and bandwidth requirements of hybrid cipher suites are different from those of classic key exchange mechanisms, we recommend that you [test them on your AWS KMS API calls](#) (p. 221) under different conditions.

## Feedback

As always, we welcome your feedback and participation in our open-source repositories. We'd especially like to hear how your infrastructure interacts with this new variant of TLS traffic.

- To provide feedback on this topic, use the **Feedback** link in the lower right corner of this page. You can also [create an issue](#) or a pull request in the [aws-kms-developer-docs](#) repository in GitHub.
- We're developing these hybrid cipher suites in open source in the [s2n](#) repository on GitHub. To provide feedback on the usability of the cipher suites, or share novel test conditions or results, [create an issue](#) in the [s2n](#) repository.
- We're writing code samples for using hybrid post-quantum TLS with AWS KMS in the [aws-kms-pq-tls-example](#) GitHub repository. To ask questions or share ideas about configuring your HTTP client or AWS KMS client to use the hybrid cipher suites, [create an issue](#) in the [aws-kms-pq-tls-example](#) repository.

## Supported AWS Regions

Post-quantum TLS for AWS KMS is available in all AWS Regions except for AWS GovCloud (US-East), AWS GovCloud (US-West), China (Beijing), and China (Ningxia).

For a list of AWS KMS endpoints for each AWS Region, see [AWS Key Management Service Endpoints and Quotas](#) in the *Amazon Web Services General Reference*. For information about FIPS endpoints, see [AWS Service Endpoints](#) in the *Amazon Web Services General Reference*.

## About Hybrid Post-Quantum Key Exchange in TLS

AWS KMS supports hybrid post-quantum key exchange cipher suites. You can use the AWS SDK for Java 2.x and AWS common runtime to configure an HTTP client to use these cipher suites. Then, whenever you connect to a AWS KMS endpoint with your HTTP client, the hybrid cipher suites are used.

This HTTP client uses [s2n](#), which is an open source implementation of the TLS protocol. s2n includes the [pq-crypto](#) module, which includes implementations of hybrid post-quantum algorithms for encryption in transit.

The hybrid cipher suites in s2n are implemented only for key exchange, not for direct data encryption. During *key exchange*, the client and server calculate the key they will use to encrypt and decrypt the data on the wire.

The algorithms that s2n uses are a *hybrid* that combines [Elliptic Curve Diffie-Hellman](#) (ECDH), a classic key exchange algorithm used today in TLS, with [Bit Flipping Key Encapsulation](#) (BIKE), a proposed post-quantum algorithm. This mechanism uses each of the algorithms independently to generate a key. Then it combines the two keys cryptographically. With s2n, you can configure an HTTP client with a *cipher preference* that places ECDH with BIKE first in the preference list. Classic key exchange algorithms are included in the preference list to ensure compatibility, but they are lower in the preference order.

If ongoing research reveals that the BIKE algorithm lacks the anticipated post-quantum strength, the hybrid key is still at least as strong as the single ECDH key currently in use. The National Institute for Standards and Technology (NIST) has [not yet standardized](#) post-quantum algorithms. They are still in the process of evaluating candidate approaches. Until that process is complete, we recommend using hybrid algorithms, rather than using post-quantum algorithms alone.

## Using Hybrid Post-Quantum TLS with AWS KMS

You can use hybrid post-quantum TLS for your calls to AWS KMS. When setting up your HTTP client test environment, be aware of the following information:

### Encryption in Transit

The hybrid cipher suites in s2n are used only for encryption in transit. They protect your data while it is traveling from your client to the AWS KMS endpoint. AWS KMS does not use these cipher suites to encrypt data under customer master keys (CMKs).

Instead, when AWS KMS encrypts your data under CMKs, it uses symmetric cryptography with 256-bit keys and the Advanced Encryption Standard in Galois Counter Mode (AES-GCM) algorithm, which is already quantum resistant. Theoretical future, large-scale quantum computing attacks on ciphertexts created under 256-bit AES-GCM keys [reduce the effective security of the key to 128 bits](#). This security level is sufficient to make brute force attacks on AWS KMS ciphertexts infeasible.

### Supported Systems

Use of the hybrid cipher suites in s2n is currently supported only on Linux systems. In addition, these cipher suites are supported only in SDKs that support the AWS common runtime, such as the AWS SDK for Java 2.x. For an example, see [How to Configure Hybrid Post-Quantum TLS \(p. 220\)](#).

## AWS KMS Endpoints

When using the hybrid cipher suites, use the standard AWS KMS endpoint. The hybrid cipher suites in s2n are not compatible with the [FIPS 140-2 validated endpoints for AWS KMS](#). Post-quantum algorithms are not allowed in a validated cryptographic module.

When you configure a HTTP client with the hybrid post-quantum cipher preference in s2n, the post-quantum ciphers are first in the cipher preference list. However, the preference list includes the classic, non-hybrid ciphers lower in the preference order for compatibility. If you were to use this cipher preference with an AWS KMS FIPS 140-2 validated endpoint, s2n negotiates a classic, non-hybrid key exchange cipher.

For a list of AWS KMS endpoints for each AWS Region, see [AWS Key Management Service Endpoints and Quotas](#) in the *Amazon Web Services General Reference*. For information about FIPS endpoints, see [AWS Service Endpoints](#) in the *Amazon Web Services General Reference*.

## Expected Performance

Our early benchmark testing shows that the hybrid cipher suites in s2n are slower than classic TLS cipher suites. The effect varies based on the network profile, CPU speed, the number of cores, and your call rate. For performance test results, see [Post-quantum TLS now supported in AWS KMS](#).

# How to Configure Hybrid Post-Quantum TLS

In this procedure, you get the `aws-crt-dev-preview` (developer preview) branch of the [AWS SDK for Java 2.x](#) from its GitHub repository. Next, you build an AWS common runtime client and add the AWS common runtime to your dependencies. Then you can configure an HTTP client that uses the hybrid post-quantum cipher preference and create an AWS KMS client that uses the HTTP client.

To see a complete working examples of configuring and using hybrid post-quantum TLS with AWS KMS, see the [aws-kms-pq-tls-example](#) repository.

1. Clone the developer preview branch ([aws-crt-dev-preview](#)) of the AWS SDK for Java 2.x.

The AWS SDK for Java 2.x is being developed in the [aws-sdk-java-v2](#) GitHub repository.

### Note

The `aws-crt-dev-preview` branch is a beta release. Your use of this library is subject to Section 1.10 ("Beta Service Participation") of the [AWS Service Terms](#).

```
$ git clone git@github.com:aws/aws-sdk-java-v2.git --branch aws-crt-dev-preview
```

2. Install and build the AWS common runtime client (`aws-crt-client`) JAR.

```
$ cd aws-sdk-java-v2
$ mvn install -Pquick
```

3. Add the AWS common runtime client to your Maven dependencies. We recommend using the latest available version.

For example, this statement adds version `2.10.7-SNAPSHOT` of the AWS common runtime client to your Maven dependencies.

```
<dependency>
  <groupId>software.amazon.awssdk</groupId>
  <artifactId>aws-crt-client</artifactId>
```

```
<version>2.10.7-SNAPSHOT</version>
</dependency>
```

4. To enable the hybrid post-quantum cipher suites, add the AWS SDK for Java 2.x to your project and initialize it. Then enable the hybrid cipher suites as shown in the following example.

This code ensures that you are working on a system that supports the hybrid cipher suite. The code then creates an HTTP client with the `TLS_CIPHER_KMS_PQ_TLSv1_0_2019_06` cipher preference that prioritizes the ECDH with BIKE hybrid cipher suite. Finally, it creates an AWS KMS client that uses the HTTP client for data transmission.

This code uses the AWS KMS asynchronous client, `KmsAsyncClient`, which calls AWS KMS asynchronously. For information about this client, see the [KmsAsyncClient Javadoc](#).

After this code completes, your [AWS KMS API](#) requests on the AWS KMS asynchronous client use the hybrid cipher suite for TLS.

```
// Check platform support
if(!TLS_CIPHER_KMS_PQ_TLSv1_0_2019_06.isSupported()){
    throw new RuntimeException("Hybrid post-quantum cipher suites are not supported on
    this platform");
}

// Configure HTTP client
SdkAsyncHttpClient awsCrtHttpClient = AwsCrtAsyncHttpClient.builder()
    .tlsCipherPreference(TLS_CIPHER_KMS_PQ_TLSv1_0_2019_06)
    .build();

// Create the KMS async client
KmsAsyncClient kmsAsync = KmsAsyncClient.builder()
    .httpClient(awsCrtHttpClient)
    .build();
```

5. Test your KMS calls with post-quantum TLS.

When you call AWS KMS API operations on the configured AWS KMS client, your calls are transmitted to the AWS KMS endpoint using hybrid post-quantum TLS. To test your configuration, run a simple KMS API call, such as [ListKeys](#).

```
ListKeysResponse keys = kmsAsync.listKeys().get();
```

## Testing Hybrid Post-Quantum TLS with AWS KMS

Consider running the following tests with hybrid cipher suites on your applications that call AWS KMS.

- Run load tests and benchmarks. The hybrid cipher suites perform differently than traditional key exchange algorithms. You might need to adjust your connection timeouts to allow for the longer handshake times. If you're running inside an AWS Lambda function, extend the execution timeout setting.
- Try connecting from different locations. Depending on the network path your request takes, you might discover that intermediate hosts, proxies, or firewalls with deep packet inspection (DPI) block the request. This might result from using the new cipher suites in the [ClientHello](#) part of the TLS handshake, or from the larger key exchange messages. If you have trouble resolving these issues, work with your security team or IT administrators to update the relevant configuration and unblock the new TLS cipher suites.

## Learn More About Post-Quantum TLS in AWS KMS

For more information about using hybrid post-quantum TLS in AWS KMS, see the following resources.

- For more information about using hybrid post-quantum TLS cipher suites with AWS KMS, including performance data, see [Post-quantum TLS now supported in AWS KMS](#).
- For information about the AWS SDK for Java 2.x, see the [AWS SDK for Java 2.x Developer Guide](#) and the [AWS SDK for Java 2.x released](#) blog post.
- For information about s2n, see [Introducing s2n, a New Open Source TLS Implementation](#) and [Using s2n](#).
- For information about the post-quantum cryptography project at the National Institute for Standards and Technology (NIST), see [Post-Quantum Cryptography](#).
- For technical information about using hybrid post-quantum key exchange in TLS, see [Hybrid Post-Quantum Key Encapsulation Methods \(PQ KEM\) for Transport Layer Security 1.2 \(TLS\)](#).

# How Key State Affects Use of a Customer Master Key

Customer master keys (CMKs) are always in one of the following states: `Enabled`, `Disabled`, `PendingImport`, `PendingDeletion`, or `Unavailable`.

The following table shows whether AWS KMS API operations that run on a CMK in each state can be expected to succeed (✓), fail (X), or succeed only under certain conditions (?). The result often differs for CMKs with imported key material.

Symmetric CMKs `Enabled`, `Disabled`, `PendingImport`, `PendingDeletion`, or `Unavailable`. Asymmetric CMKs can be in the `Enabled`, `Disabled`, or `PendingDeletion` key state.

The `Unavailable` state applies only to a CMK in a [custom key store \(p. 172\)](#). A CMK in a custom key store is `Unavailable` when the custom key store is intentionally disconnected from its AWS CloudHSM cluster. You can view and manage unavailable CMKs, but you cannot use them in cryptographic operations.

## Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

The following API operations do not appear in the table because they do not use an existing CMK.

- `ConnectCustomKeyStore`
- `CreateCustomKeyStore`
- `CreateKey`
- `DeleteCustomKeyStore`
- `DescribeCustomKeyStores`
- `DisconnectCustomKeyStore`
- `GenerateRandom`
- `UpdateCustomKeyStore`

**Table Details**

- [1] DisabledException: `<CMK ARN>` is disabled.
- [2] DisabledException: `<CMK ARN>` is pending deletion.
- [3] KMSInvalidStateException: `<CMK ARN>` is pending deletion.

- [4] `KMSInvalidStateException`: `<CMK ARN>` is not pending deletion.
- [5] `KMSInvalidStateException`: `<CMK ARN>` is pending import.
- [6] `UnsupportedOperationException`: `<CMK ARN>` origin is `EXTERNAL` which is not valid for this operation.
- [7] If the CMK has imported key material or is in a custom key store: `UnsupportedOperationException`.
- [8] If the CMK has imported key material: `KMSInvalidStateException`
- [9] If the CMK cannot or does not have imported key material: `UnsupportedOperationException`.
- [10] If the source CMK is pending deletion, the command succeeds. If the destination CMK is pending deletion, the command fails with error: `KMSInvalidStateException` : `<CMK ARN>` is pending deletion.
- [11] `KMSInvalidStateException`: `<CMK ARN>` is unavailable. You cannot perform this operation on an unavailable CMK.
- [12] The operation succeeds, but the key state of the CMK does not change until it becomes available.
- [13] While a CMK in a custom key store is pending deletion, its key state remains `PendingDeletion` even if the CMK becomes unavailable. This allows you to cancel deletion of the CMK at any time during the waiting period.

# How AWS Services use AWS KMS

Many AWS services use AWS KMS to support encryption of your data. When an AWS service is integrated with AWS KMS, you can use the customer master keys (CMKs) in your account to protect the data that the service receives, stores, or manages for you. For the complete list of AWS services that are integrated with AWS KMS, see [AWS Service Integration](#).

The following topics discuss in detail how particular services use AWS KMS, including the CMKs they support, how they manage data keys, the permissions they require, and how to track each service's use of the CMKs in your account.

## **Important**

AWS services that integrate with AWS KMS support only symmetric CMKs. They do not support asymmetric CMKs. For details, see the encryption topic in the documentation for the service.

## How AWS CloudTrail Uses AWS KMS

You can use AWS CloudTrail to record AWS API calls and other activity for your AWS account and to save the recorded information to log files in an Amazon Simple Storage Service (Amazon S3) bucket that you choose. By default, the log files delivered by CloudTrail to your S3 bucket are encrypted using server-side encryption with Amazon S3–managed encryption keys (SSE-S3). But you can choose instead to use server-side encryption with AWS KMS–managed keys (SSE-KMS). To learn how to encrypt your CloudTrail log files with AWS KMS, see [Encrypting CloudTrail Log Files with AWS KMS–Managed Keys \(SSE-KMS\)](#) in the *AWS CloudTrail User Guide*.

## **Important**

AWS CloudTrail and Amazon S3 support only [symmetric customer master keys \(p. 130\)](#) (CMKs). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your CloudTrail Logs. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

## **Topics**

- [Understanding When Your CMK is Used \(p. 228\)](#)
- [Understanding How Often Your CMK is Used \(p. 232\)](#)

## Understanding When Your CMK is Used

Encrypting CloudTrail log files with AWS KMS builds on the Amazon S3 feature called server-side encryption with AWS KMS–managed keys (SSE-KMS). To learn more about SSE-KMS, see [How Amazon Simple Storage Service \(Amazon S3\) Uses AWS KMS \(p. 265\)](#) in this guide or [Protecting Data Using Server-Side Encryption with AWS KMS–Managed Keys \(SSE-KMS\)](#) in the *Amazon Simple Storage Service Developer Guide*.

When you configure AWS CloudTrail to use SSE-KMS to encrypt your log files, CloudTrail and Amazon S3 use your KMS customer master key (CMK) when you perform certain actions with those services. The following sections explain when and how those services can use your CMK, and provide additional information that you can use to validate this explanation.

### Actions that cause CloudTrail and Amazon S3 to use your CMK

- [You Configure CloudTrail to Encrypt Log Files with Your Customer Master Key \(CMK\) \(p. 229\)](#)
- [CloudTrail Puts a Log File into Your S3 Bucket \(p. 230\)](#)
- [You Get an Encrypted Log File from Your S3 Bucket \(p. 231\)](#)

## You Configure CloudTrail to Encrypt Log Files with Your Customer Master Key (CMK)

When you [update your CloudTrail configuration to use your CMK](#), CloudTrail sends a [GenerateDataKey](#) request to AWS KMS to verify that the CMK exists and that CloudTrail has permission to use it for encryption. CloudTrail does not use the resulting data key.

The `GenerateDataKey` request includes the following information for the [encryption context \(p. 12\)](#):

- The [Amazon Resource Name \(ARN\)](#) of the CloudTrail trail
- The ARN of the S3 bucket and path where the CloudTrail log files are delivered

The `GenerateDataKey` request results in an entry in your CloudTrail logs similar to the following example. When you see a log entry like this one, you can determine that CloudTrail (1) called the AWS KMS (2) `GenerateDataKey` operation (3) for a specific trail (4). AWS KMS created the data key under a specific CMK (5).

## CloudTrail Puts a Log File into Your S3 Bucket

Each time CloudTrail puts a log file into your S3 bucket, Amazon S3 sends a [GenerateDataKey](#) request to AWS KMS on behalf of CloudTrail. In response to this request, AWS KMS generates a unique data key and then sends Amazon S3 two copies of the data key, one in plaintext and one that is encrypted with the specified CMK. Amazon S3 uses the plaintext data key to encrypt the CloudTrail log file and then removes the plaintext data key from memory as soon as possible after use. Amazon S3 stores the encrypted data key as metadata with the encrypted CloudTrail log file.

The `GenerateDataKey` request includes the following information for the [encryption context](#) (p. 12):

- The [Amazon Resource Name \(ARN\)](#) of the CloudTrail trail
- The ARN of the S3 object (the CloudTrail log file)

Each `GenerateDataKey` request results in an entry in your CloudTrail logs similar to the following example. When you see a log entry like this one, you can determine that CloudTrail (**1**) called the AWS KMS (**2**) `GenerateDataKey` operation (**3**) for a specific trail (**4**) to protect a specific log file (**5**). AWS KMS created the data key under the specified CMK (**6**), shown twice in the same log entry.

### Note

You might need to scroll to the right to see some of the callouts in the following example log entry.

```

    "accountId": "111122223333"
  }],
  "eventType": "AwsServiceEvent",
  "recipientAccountId": "111122223333"
}

```

## You Get an Encrypted Log File from Your S3 Bucket

Each time you get an encrypted CloudTrail log file from your S3 bucket, Amazon S3 sends a [Decrypt](#) request to AWS KMS on your behalf to decrypt the log file's encrypted data key. In response to this request, AWS KMS uses your CMK to decrypt the data key and then sends the plaintext data key to Amazon S3. Amazon S3 uses the plaintext data key to decrypt the CloudTrail log file and then removes the plaintext data key from memory as soon as possible after use.

The Decrypt request includes the following information for the [encryption context](#) (p. 12):

- The [Amazon Resource Name \(ARN\)](#) of the CloudTrail trail
- The ARN of the S3 object (the CloudTrail log file)

Each Decrypt request results in an entry in your CloudTrail logs similar to the following example. When you see a log entry like this one, you can determine that an IAM user in your AWS account (**(1)**) called the AWS KMS (**(2)**) Decrypt operation (**(3)**) for a specific trail (**(4)**) and a specific log file (**(5)**). AWS KMS decrypted the data key under a specific CMK (**(6)**).

### Note

```

## Understanding How Often Your CMK is Used

To predict costs and better understand your AWS bill, you might want to know how often CloudTrail uses your CMK. AWS KMS charges for all API requests to the service that exceed the free tier. For the exact charges, see [AWS Key Management Service Pricing](#).

When you encrypt CloudTrail log files with AWS KMS–Managed Keys (SSE-KMS), each time [CloudTrail puts a log file into your S3 bucket \(p. 230\)](#) it results in an AWS KMS API request. Typically, CloudTrail puts a log file into your S3 bucket once every five minutes, which results in approximately 288 AWS KMS API requests per day, per region, and per AWS account. For example:

- If you enable this feature in two regions in a single AWS account, you can expect approximately 576 AWS KMS API requests per day (2 x 288).
- If you enable this feature in two regions in each of three AWS accounts, you can expect approximately 1,728 AWS KMS API requests per day (6 x 288).

These numbers represent only the AWS KMS calls that result from `PUT` requests. They do not count the [decrypt](#) calls to AWS KMS that result from `GET` requests when you get an encrypted log file from your S3 bucket.

## How Amazon DynamoDB Uses AWS KMS

[Amazon DynamoDB](#) is a fully managed, scalable NoSQL database service. DynamoDB integrates with AWS Key Management Service (AWS KMS) to support the [encryption at rest](#) server-side encryption feature.

With *encryption at rest*, DynamoDB transparently encrypts all customer data in a DynamoDB table, including its primary key and local and global [secondary indexes](#), whenever the table is persisted to disk. (If your table has a sort key, some of the sort keys that mark range boundaries are stored in plaintext in the table metadata.) When you access your table, DynamoDB decrypts the table data transparently. You do not need to change your applications to use or manage encrypted tables.

Encryption at rest also protects [DynamoDB streams](#), [global tables](#), and [backups](#) whenever these objects are saved to durable media. Statements about tables in this topic apply to these objects, too.

All DynamoDB tables are encrypted. There is no option to enable or disable encryption for new or existing tables. By default, all tables are encrypted under an [AWS owned customer master key](#) (p. 4) (CMK) in the DynamoDB service account. However, you can select an option to encrypt some or all of your tables under a [customer managed CMK](#) (p. 3) or the [AWS managed CMK](#) (p. 4) for DynamoDB in your account.

### Note

Before November 2018, encryption at rest was an optional feature that supported only the AWS managed CMK for DynamoDB. If you enabled encryption at rest on any of your DynamoDB tables, they will continue to be encrypted under the AWS managed CMK unless you use the AWS Management Console or [UpdateTable](#) operation to switch to a customer managed CMK or an AWS owned CMK.

### Client-Side Encryption for DynamoDB

In addition to encryption at rest, which is a *server-side encryption* feature, AWS provides the [Amazon DynamoDB Encryption Client](#). This *client-side encryption* library enables you to protect your table data before submitting it to DynamoDB. With server-side encryption, your data is encrypted in transit over an HTTPS connection, decrypted at the DynamoDB endpoint, and then re-encrypted before being stored in DynamoDB. Client-side encryption provides end-to-end protection for your data from its source to storage in DynamoDB.

You can use the DynamoDB Encryption Client along with encryption at rest. To help you decide if this strategy is right for your DynamoDB data, see [Client-Side or Server-Side Encryption?](#) in the *Amazon DynamoDB Encryption Client Developer Guide*.

### Topics

- [Using CMKs and Data Keys](#) (p. 233)
- [Authorizing Use of Your CMK](#) (p. 235)
- [DynamoDB Encryption Context](#) (p. 239)
- [Monitoring DynamoDB Interaction with AWS KMS](#) (p. 239)

## Using CMKs and Data Keys

The DynamoDB encryption at rest feature uses an AWS KMS customer master key (CMK) and a hierarchy of data keys to protect your table data. DynamoDB uses the same key hierarchy to protect DynamoDB streams, global tables, and backups when they are written to durable media.

## Customer Master Key (CMK)

Encryption at rest protects your DynamoDB tables under an AWS KMS customer master key (CMK). By default, it uses an [AWS owned CMK \(p. 4\)](#), a multi-tenant key that is created and managed in a DynamoDB service account. But DynamoDB supports an option to encrypt some or all of your tables under a [customer managed CMKs \(p. 3\)](#) or the [AWS managed CMK \(p. 4\)](#) for DynamoDB (aws/dynamodb) in your AWS account. You can select the CMK for a table when you create or update the table, and you can make a different choice for each table.

### Important

DynamoDB supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your DynamoDB tables. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

You can choose your CMK in the DynamoDB console or by using DynamoDB API. When you select a CMK for a table, the local and global secondary indexes, streams, and backups are encrypted with the same CMK. However, you cannot use a customer managed CMK to encrypt DynamoDB global table replicas. To encrypt replicas, use an AWS owned CMK or an AWS managed CMK.

You can change the CMK for a table at any time, either in the DynamoDB console or by using the [UpdateTable](#) operation. The process of switching keys is seamless and does not require downtime or degrade service.

Use a customer managed CMK to get the following features:

- You create and manage the CMK, including setting the [key policies \(p. 50\)](#), [IAM policies \(p. 67\)](#) and [grants \(p. 115\)](#) to control access to the CMK. You can [enable and disable \(p. 41\)](#) the CMK, enable and disable [automatic key rotation \(p. 142\)](#), and [delete the CMK \(p. 160\)](#) when it is no longer in use.
- You can use a customer managed CMK with [imported key material \(p. 147\)](#) or a customer managed CMK in a [custom key store \(p. 172\)](#) that you own and manage.
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in [AWS CloudTrail logs \(p. 239\)](#).

Use the AWS managed CMK if you need any of the following features:

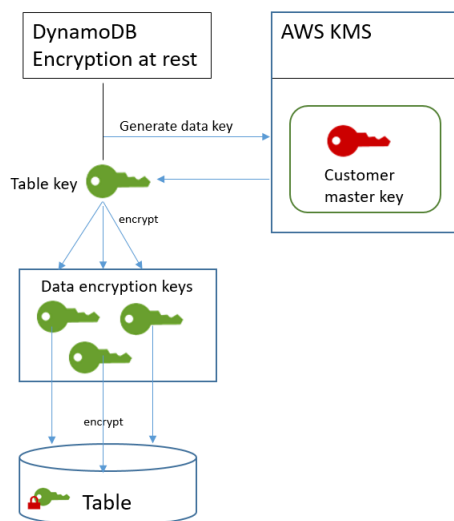

- You can [view the CMK \(p. 22\)](#) and [view its key policy \(p. 61\)](#). (You cannot change the key policy.)
- You can audit the encryption and decryption of your DynamoDB table by examining the DynamoDB API calls to AWS KMS in [AWS CloudTrail logs \(p. 239\)](#).

However, the AWS owned CMK is free of charge and its use does not count against [AWS KMS limits \(p. 353\)](#). Customer managed CMKs and AWS managed CMKs [incur a charge](#) for each API call and AWS KMS limits apply to these CMKs.

## Table Keys

DynamoDB uses the CMK for the table to generate and encrypt a unique [data key \(p. 4\)](#) for the table, known as the *table key*. The table key persists for the lifetime of the encrypted table.

The table key is used as a key encryption key. DynamoDB uses this table key to protect data encryption keys that are used to encrypt the table data. DynamoDB generates a unique data encryption key for each underlying structure in a table, but multiple table items might be protected by the same data encryption key.

When you first access an encrypted table, DynamoDB sends a request to AWS KMS to use the CMK to decrypt the table key. Then, it uses the plaintext table key to decrypt the data encryption keys, and uses the plaintext data encryption keys to decrypt table data.

DynamoDB generates, uses, and stores the table key and data encryption keys outside of AWS KMS. It protects all keys with [Advanced Encryption Standard \(AES\)](#) encryption and 256-bit encryption keys. Then, it stores the encrypted keys with the encrypted data so they are available to decrypt the table data on demand.

If you change the CMK for your table, DynamoDB generates a new table key. Then, it uses the new table key to re-encrypt the data encryption keys.

### Table Key Caching

To avoid calling AWS KMS for every DynamoDB operation, DynamoDB caches the plaintext table keys for each connection in memory. If DynamoDB gets a request for the cached table key after five minutes of inactivity, it sends a new request to AWS KMS to decrypt the table key. This call will capture any changes made to the access policies of the CMK in AWS KMS or AWS Identity and Access Management (IAM) since the last request to decrypt the table key.

## Authorizing Use of Your CMK

If you use a [customer managed CMK \(p. 3\)](#) or the [AWS managed CMK \(p. 4\)](#) in your account to protect your DynamoDB table, the policies on that CMK must give DynamoDB permission to use it on your behalf. The authorization context on the AWS managed CMK for DynamoDB includes its key policy and grants that delegate the permissions to use it.

You have full control over the policies and grants on a customer managed CMK. Because the AWS managed CMK is in your account, you can view its policies and grants. But, because it is managed by AWS, you cannot change the policies.

DynamoDB does not need additional authorization to use the default [AWS owned CMK \(p. 2\)](#) to protect the DynamoDB tables in your AWS account.

### Topics

- [AWS Managed CMK Key Policy \(p. 236\)](#)

- [Customer Managed CMK Key Policy \(p. 237\)](#)
- [Using Grants to Authorize DynamoDB \(p. 238\)](#)

## AWS Managed CMK Key Policy

When DynamoDB uses the [AWS managed CMK \(p. 4\)](#) for DynamoDB (aws/dynamodb) in cryptographic operations, it does so on behalf of the user who is accessing the [DynamoDB resource](#). The key policy on the AWS managed CMK gives all users in the account permission to use the AWS managed CMK for specified operations. But permission is granted only when DynamoDB makes the request on the user's behalf. The [ViaService condition \(p. 111\)](#) in the key policy does not allow any user to use the AWS managed CMK unless the request originates with the DynamoDB service.

This key policy, like the policies of all AWS managed keys, is established by AWS. You cannot change it, but you can view it at any time. For details, see [Viewing a Key Policy \(p. 61\)](#).

The policy statements in the key policy have the following effect:

- Allow users in the account to use the AWS managed CMK for DynamoDB in cryptographic operations when the request comes from DynamoDB on their behalf. The policy also allows users to [create grants \(p. 238\)](#) for the CMK.
- Allows the AWS account root user to view the properties of the AWS managed CMK for DynamoDB and to [revoke the grant](#) that allows DynamoDB to use the CMK. DynamoDB uses [grants \(p. 238\)](#) for ongoing maintenance operations.
- Allows DynamoDB to perform read-only operations to find the AWS managed CMK for DynamoDB in your account.

    "Resource" : "*"   
  } ]  
}
```

## Customer Managed CMK Key Policy

When you select a [customer managed CMK \(p. 3\)](#) to protect a DynamoDB table, DynamoDB gets permission to use the CMK on behalf of the principal who makes the selection. That principal, a user or role, must have the permissions on the CMK that DynamoDB requires. You can provide these permissions in a [key policy \(p. 50\)](#), an [IAM policy \(p. 67\)](#), or a [grant \(p. 115\)](#).

At a minimum, DynamoDB requires the following permissions on a customer managed CMK:

- [kms:Encrypt](#)
- [kms:Decrypt](#)
- [kms:ReEncrypt\\*](#) (for [kms:ReEncryptFrom](#) and [kms:ReEncryptTo](#))
- [kms:GenerateDataKey\\*](#) (for [kms:GenerateDataKey](#) and [kms:GenerateDataKeyWithoutPlaintext](#))
- [kms:DescribeKey](#)
- [kms:CreateGrant](#)

For example, the following example key policy provides only the required permissions. The policy has the following effects:

- Allows DynamoDB to use the CMK in cryptographic operations and create grants, but only when it is acting on behalf of principals in the account who have permission to use DynamoDB. If the principals specified in the policy statement don't have permission to use DynamoDB, the call fails, even when it comes from the DynamoDB service.
- The [kms:ViaService \(p. 111\)](#) condition key allows the permissions only when the request comes from DynamoDB on behalf of the principals listed in the policy statement. These principals can't call these operations directly. Note that the `kms:ViaService` value, `dynamodb.*.amazonaws.com`, has an asterisk (\*) in the Region position. DynamoDB requires the permission to be independent of any particular AWS Region so it can make cross-Region calls to support [DynamoDB global tables](#).
- Gives the CMK administrators (users who can assume the `db-team` role) read-only access to the CMK and permission to revoke grants, including the [grants that DynamoDB requires \(p. 238\)](#) to protect the table.
- Gives DynamoDB read-only access to the CMK. In this case, DynamoDB can call these operations directly. It does not have to act on behalf of an account principal.

Before using an example key policy, replace the example principals with actual principals from your AWS account.

```

        "Resource": "*"
    }
]
}

```

## Using Grants to Authorize DynamoDB

In addition to key policies, DynamoDB uses grants to set permissions on a customer managed CMK or the AWS managed CMK for DynamoDB (aws/dynamodb). To view the grants on a CMK in your account, use the [ListGrants](#) operation. DynamoDB does not need grants, or any additional permissions, to use the [AWS owned CMK](#) (p. 4) to protect your table.

DynamoDB uses the grant permissions when it performs background system maintenance and continuous data protection tasks. It also uses grants to generate [table keys](#) (p. 233).

Each grant is specific to a table. If the account includes multiple tables encrypted under the same CMK, there is a grant of each type for each table. The grant is constrained by the [DynamoDB encryption context](#) (p. 239), which includes the table name and the AWS account ID, and it includes permission to the [retire the grant](#) if it is no longer needed.

To create the grants, DynamoDB must have permission to call `CreateGrant` on behalf of the user who created the encrypted table. For AWS managed CMKs, DynamoDB gets `kms:CreateGrant` permission from the [key policy \(p. 236\)](#), which allows account users to call `CreateGrant` on the CMK only when DynamoDB makes the request on an authorized user's behalf.

The key policy can also allow the account to [revoke the grant](#) on the CMK. However, if you revoke the grant on an active encrypted table, DynamoDB will not be able to protect and maintain the table.

## DynamoDB Encryption Context

An [encryption context \(p. 12\)](#) is a set of key–value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

DynamoDB uses the same encryption context in all AWS KMS cryptographic operations. If you use a [customer managed CMK \(p. 3\)](#) or an [AWS managed CMK \(p. 4\)](#) to protect your DynamoDB table, you can use the encryption context to identify use of the CMK in audit records and logs. It also appears in plaintext in logs, such as [AWS CloudTrail](#) and [Amazon CloudWatch Logs](#).

The encryption context can also be used as a condition for authorization in policies and grants. DynamoDB uses the encryption context to constrain the [grants \(p. 238\)](#) that allow access to the customer managed CMK or AWS managed CMK in your account and region.

In its requests to AWS KMS, DynamoDB uses an encryption context with two key–value pairs.

```
"encryptionContextSubset": {  
  "aws:dynamodb:tableName": "Books"  
  "aws:dynamodb:subscriberId": "111122223333"  
}
```

- **Table** – The first key–value pair identifies the table that DynamoDB is encrypting. The key is `aws:dynamodb:tableName`. The value is the name of the table.

```
"aws:dynamodb:tableName": "<table-name>"
```

For example:

```
"aws:dynamodb:tableName": "Books"
```

- **Account** – The second key–value pair identifies the AWS account. The key is `aws:dynamodb:subscriberId`. The value is the account ID.

```
"aws:dynamodb:subscriberId": "<account-id>"
```

For example:

```
"aws:dynamodb:subscriberId": "111122223333"
```

## Monitoring DynamoDB Interaction with AWS KMS

If you use a [customer managed CMK \(p. 3\)](#) or an [AWS managed CMK \(p. 4\)](#) to protect your DynamoDB tables, you can use AWS CloudTrail logs to track the requests that DynamoDB sends to AWS KMS on your behalf.

The `GenerateDataKey`, `Decrypt`, and `CreateGrant` requests are discussed in this section. In addition, DynamoDB uses a [DescribeKey](#) operation to determine whether the CMK you selected exists in the account and region. It also uses a [RetireGrant](#) operation to remove a grant when you delete a table.

### GenerateDataKey

When you enable encryption at rest on a table, DynamoDB creates a unique table key. It sends a [GenerateDataKey](#) request to AWS KMS that specifies the CMK for the table.

The event that records the `GenerateDataKey` operation is similar to the following example event. The user is the DynamoDB service account. The parameters include the Amazon Resource Name (ARN) of the CMK, a key specifier that requires a 256-bit key, and the [encryption context](#) (p. 239) that identifies the table and the AWS account.

```

}
```

### Decrypt

When you access an encrypted DynamoDB table, DynamoDB needs to decrypt the table key so that it can decrypt the keys below it in the hierarchy. It then decrypts the data in the table. To decrypt the table key, DynamoDB sends a [Decrypt](#) request to AWS KMS that specifies the CMK for the table.

The event that records the `Decrypt` operation is similar to the following example event. The user is the principal in your AWS account who is accessing the table. The parameters include the encrypted table key (as a ciphertext blob) and the [encryption context](#) (p. 239) that identifies the table and the AWS account. AWS KMS derives the ID of the CMK from the ciphertext.

}
```

## CreateGrant

When you use a [customer managed CMK \(p. 3\)](#) or an [AWS managed CMK \(p. 4\)](#) to protect your DynamoDB table, DynamoDB uses [grants \(p. 238\)](#) to allow the service to perform continuous data protection and maintenance and durability tasks. These grants are not required on [AWS owned CMKs \(p. 4\)](#).

The grants that DynamoDB creates are specific to a table. The principal in the [CreateGrant](#) request is the user who created the table.

The event that records the `CreateGrant` operation is similar to the following example event. The parameters include the Amazon Resource Name (ARN) of the CMK for the table, the grantee principal (the DynamoDB service), and the operations that the grant covers. It also includes a constraint that requires all encryption operation use the specified [encryption context](#) (p. 239).

```

## How Amazon Elastic Block Store (Amazon EBS) Uses AWS KMS

This topic discusses in detail how [Amazon Elastic Block Store \(Amazon EBS\)](#) uses AWS KMS to encrypt volumes and snapshots. For basic instructions about encrypting Amazon EBS volumes, see [Amazon EBS Encryption](#).

### Topics

- [Amazon EBS Encryption \(p. 243\)](#)
- [Using CMKs and Data Keys \(p. 243\)](#)
- [Amazon EBS Encryption Context \(p. 244\)](#)
- [Detecting Amazon EBS Failures \(p. 244\)](#)
- [Using AWS CloudFormation to Create Encrypted Amazon EBS Volumes \(p. 245\)](#)

## Amazon EBS Encryption

When you attach an encrypted Amazon EBS volume to a [supported Amazon Elastic Compute Cloud \(Amazon EC2\) instance type](#), data stored at rest on the volume, disk I/O, and snapshots created from the volume are all encrypted. The encryption occurs on the servers that host Amazon EC2 instances.

This feature is supported on all [Amazon EBS volume types](#). You access encrypted volumes the same way you access other volumes; encryption and decryption are handled transparently and they require no additional action from you, your EC2 instance, or your application. Snapshots of encrypted volumes are automatically encrypted, and volumes that are created from encrypted snapshots are also automatically encrypted.

The encryption status of an EBS volume is determined when you create the volume. You cannot change the encryption status of an existing volume. However, you can [migrate data](#) between encrypted and unencrypted volumes and apply a new encryption status while copying a snapshot.

## Using CMKs and Data Keys

When you [create an encrypted Amazon EBS volume](#), you specify an AWS KMS customer master key (CMK). By default, Amazon EBS uses the [AWS managed CMK \(p. 4\)](#) for Amazon EBS in your account. However, you can specify a [customer managed CMK \(p. 3\)](#).

### Important

Amazon EBS supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt an Amazon EBS volume. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

Amazon EBS uses the CMK that you specify to generate a unique data key for each volume. It stores an encrypted copy of the data key with the volume. Then, when you attach the volume to an Amazon EC2 instance, Amazon EBS uses the data key to encrypt all disk I/O to the volume.

The following explains how Amazon EBS uses your CMK:

1. When you create an encrypted EBS volume, Amazon EBS sends a [GenerateDataKeyWithoutPlaintext](#) request to AWS KMS, specifying the CMK that you chose for EBS volume encryption.
2. AWS KMS generates a new data key, encrypts it under the specified CMK, and then sends the encrypted data key to Amazon EBS to store with the volume metadata.
3. When you attach the encrypted volume to an EC2 instance, Amazon EC2 sends the encrypted data key to AWS KMS with a [Decrypt](#) request.
4. AWS KMS decrypts the encrypted data key and then sends the decrypted (plaintext) data key to Amazon EC2.
5. Amazon EC2 uses the plaintext data key in hypervisor memory to encrypt disk I/O to the EBS volume. The plaintext data key persists in memory as long as the EBS volume is attached to the EC2 instance.

## Amazon EBS Encryption Context

In its [GenerateDataKeyWithoutPlaintext](#) and [Decrypt](#) requests to AWS KMS, Amazon EBS uses an encryption context with a name-value pair that identifies the volume or snapshot in the request. The name in the encryption context does not vary.

An [encryption context](#) (p. 12) is a set of key-value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

For all volumes and for encrypted snapshots created with the Amazon EBS [CreateSnapshot](#) operation, Amazon EBS uses the volume ID as encryption context value. In the `requestParameters` field of a CloudTrail log entry, the encryption context looks similar to the following:

```
"encryptionContext": {  
  "aws:ebs:id": "vol-0cfb133e847d28be9"  
}
```

For encrypted snapshots created with the Amazon EC2 [CopySnapshot](#) operation, Amazon EBS uses the snapshot ID as encryption context value. In the `requestParameters` field of a CloudTrail log entry, the encryption context looks similar to the following:

```
"encryptionContext": {  
  "aws:ebs:id": "snap-069a655b568de654f"  
}
```

## Detecting Amazon EBS Failures

To create an encrypted EBS volume or attach the volume to an EC2 instance, Amazon EBS and the Amazon EC2 infrastructure must be able to use the CMK that you specified for EBS volume encryption. When the CMK is not usable—for example, when its [key state](#) (p. 223) is not `Enabled`—the volume creation or volume attachment fails.

In this case, Amazon EBS sends an *event* to Amazon CloudWatch Events to notify you about the failure. With CloudWatch Events, you can establish rules that trigger automatic actions in response to these

events. For more information, see [Amazon CloudWatch Events for Amazon EBS](#) in the *Amazon EC2 User Guide for Linux Instances*, especially the following sections:

- [Invalid Encryption Key on Volume Attach or Reattach](#)
- [Invalid Encryption Key on Create Volume](#)

To fix these failures, ensure that the CMK that you specified for EBS volume encryption is enabled. To do this, first [view the CMK \(p. 22\)](#) to determine its current key state (the **Status** column in the AWS Management Console). Then, see the information at one of the following links:

- If the CMK's key state is disabled, [enable it \(p. 41\)](#).
- If the CMK's key state is pending import, [import key material \(p. 148\)](#).
- If the CMK's key state is pending deletion, [cancel key deletion \(p. 162\)](#).

## Using AWS CloudFormation to Create Encrypted Amazon EBS Volumes

You can use [AWS CloudFormation](#) to create encrypted Amazon EBS volumes. For more information, see [AWS::EC2::Volume](#) in the *AWS CloudFormation User Guide*.

## How Amazon Elastic Transcoder Uses AWS KMS

You can use Amazon Elastic Transcoder to convert media files stored in an Amazon S3 bucket into formats required by consumer playback devices. Both input and output files can be encrypted and decrypted. The following sections discuss how AWS KMS is used for both processes.

### Topics

- [Encrypting the input file \(p. 245\)](#)
- [Decrypting the input file \(p. 246\)](#)
- [Encrypting the output file \(p. 247\)](#)
- [HLS Content Protection \(p. 248\)](#)
- [Elastic Transcoder Encryption Context \(p. 248\)](#)

## Encrypting the input file

Before you can use Elastic Transcoder, you must [create an Amazon S3 bucket](#) and upload your media file into it. You can encrypt the file before uploading by using AES client-side encryption or after uploading by using Amazon S3 server-side encryption.

If you choose client-side encryption using AES, you are responsible for encrypting the file before uploading it to Amazon S3, and you must provide Elastic Transcoder access to the encryption key. You do this by using a [symmetric \(p. 130\)](#) AWS KMS [customer master key \(p. 2\)](#) (CMK) to protect the AES encryption key you used to encrypt the media file.

If you choose server-side encryption, you are allowing Amazon S3 to perform all encryption and decryption of files on your behalf. You can configure Amazon S3 to use one of three different master keys to protect the unique data key used to encrypt your file:

- The Amazon S3 master key, a key that is owned and managed by AWS

- The [AWS managed CMK \(p. 4\)](#) for Amazon S3, a master key that is owned by your account, but managed by AWS
- Any [symmetric \(p. 130\) customer managed CMK \(p. 3\)](#) that you create by using AWS KMS

### Important

For both client-side and server-side encryption, Elastic Transcoder supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your Elastic Transcoder files. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

You can request encryption and the master key you want by using the Amazon S3 console or the appropriate Amazon S3 APIs. For more information about how Amazon S3 performs encryption, see [Protecting Data Using Encryption](#) in the *Amazon Simple Storage Service Developer Guide*.

When you protect your input file by using the AWS managed CMK for Amazon S3 in your account or a customer managed CMK, Amazon S3 and AWS KMS interact in the following manner:

1. Amazon S3 requests a plaintext data key and a copy of the data key encrypted under the specified CMK.
2. AWS KMS creates a data key, encrypts it with the specified CMK, and then sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 uses the plaintext data key to encrypt the media file and then stores the file in the specified Amazon S3 bucket.
4. Amazon S3 stores the encrypted data key alongside of the encrypted media file.

## Decrypting the input file

If you choose Amazon S3 server-side encryption to encrypt the input file, Elastic Transcoder does not decrypt the file. Instead, Elastic Transcoder relies on Amazon S3 to perform decryption depending on the [settings you specify when you create a job](#) and a pipeline.

The following combination of settings are available.

Encryption mode	AWS KMS key	Meaning
<b>S3</b>	Default	Amazon S3 creates and manages the keys used to encrypt and decrypt the media file. The process is opaque to the user.
<b>S3-AWS-KMS</b>	Default	Amazon S3 uses a data key encrypted by the default AWS managed CMK for Amazon S3 in your account to encrypt the media file.
<b>S3-AWS-KMS</b>	Custom (with ARN)	Amazon S3 uses a data key encrypted by the specified customer managed CMK to encrypt the media file.

When **S3-AWS-KMS** is specified, Amazon S3 and AWS KMS work together in the following manner to perform the decryption.

1. Amazon S3 sends the encrypted data key to AWS KMS.
2. AWS KMS decrypts the data key by using the appropriate CMK, and then sends the plaintext data key back to Amazon S3.
3. Amazon S3 uses the plaintext data key to decrypt the ciphertext.

If you choose client-side encryption using an AES key, Elastic Transcoder retrieves the encrypted file from the Amazon S3 bucket and decrypts it. Elastic Transcoder uses the CMK you specified when you created the pipeline to decrypt the AES key and then uses the AES key to decrypt the media file.

## Encrypting the output file

Elastic Transcoder encrypts the output file depending on how you specify the encryption settings when you create a job and a pipeline. The following options are available.

Encryption mode	AWS KMS key	Meaning
<b>S3</b>	Default	Amazon S3 creates and manages the keys used to encrypt the output file.
<b>S3-AWS-KMS</b>	Default	Amazon S3 uses a data key created by AWS KMS and encrypted by the AWS managed CMK for Amazon S3 in your account.
<b>S3-AWS-KMS</b>	Custom (with ARN)	Amazon S3 uses a data key encrypted by using the customer managed CMK specified by the ARN to encrypt the media file.
<b>AES-</b>	Default	Elastic Transcoder uses the AWS managed CMK for Amazon S3 in your account to decrypt the specified AES key you provide and uses that key to encrypt the output file.
<b>AES-</b>	Custom (with ARN)	Elastic Transcoder uses the customer managed CMK specified by the ARN to decrypt the specified AES key you provide and uses that key to encrypt the output file.

When you specify that the AWS managed CMK for Amazon S3 in your account or a customer managed CMK is used to encrypt the output file, Amazon S3 and AWS KMS interact in the following manner:

1. Amazon S3 requests a plaintext data key and a copy of the data key encrypted under the specified CMK.
2. AWS KMS creates a data key, encrypts it under the CMK, and sends both the plaintext data key and the encrypted data key to Amazon S3.
3. Amazon S3 encrypts the media using the data key and stores it in the specified Amazon S3 bucket.
4. Amazon S3 stores the encrypted data key alongside the encrypted media file.

When you specify that your provided AES key be used to encrypt the output file, the AES key must be encrypted using a CMK in AWS KMS. Elastic Transcoder, AWS KMS, and you interact in the following manner:

1. You encrypt your AES key by calling the [Encrypt](#) operation in the AWS KMS API. AWS KMS encrypts the key by using the specified CMK. You specify which CMK to use when you are creating the pipeline.
2. You specify the file containing the encrypted AES key when you create the Elastic Transcoder job.
3. Elastic Transcoder decrypts the key by calling the [Decrypt](#) operation in the AWS KMS API, passing the encrypted key as ciphertext.
4. Elastic Transcoder uses the decrypted AES key to encrypt the output media file and then deletes the decrypted AES key from memory. Only the encrypted copy you originally defined in the job is saved to disk.
5. You can download the encrypted output file and decrypt it locally by using the original AES key that you defined.

**Important**

AWS never stores your private encryption keys. Therefore, it is important that you manage your keys safely and securely. If you lose them, you won't be able to decrypt your data.

## HLS Content Protection

HTTP Live Streaming (HLS) is an adaptive streaming protocol. Elastic Transcoder supports HLS by breaking your input file into smaller individual files called *media segments*. A set of corresponding individual media segments contain the same material encoded at different bit rates, thereby enabling the player to select the stream that best fits the available bandwidth. Elastic Transcoder also creates playlists that contain metadata for the various segments that are available to be streamed.

When you enable *HLS content protection*, each media segment is encrypted using a 128-bit AES encryption key. When the content is viewed, during the playback process, the player downloads the key and decrypts the media segments.

Two types of keys are used: an AWS KMS CMK and a data key. You must create a CMK to use to encrypt and decrypt the data key. Elastic Transcoder uses the data key to encrypt and decrypt media segments. The data key must be AES-128. All variations and segments of the same content are encrypted using the same data key. You can provide a data key or have Elastic Transcoder create it for you.

The CMK can be used to encrypt the data key at the following points:

- If you provide your own data key, you must encrypt it before passing it to Elastic Transcoder.
- If you request that Elastic Transcoder generate the data key, then Elastic Transcoder encrypts the data key for you.

The CMK can be used to decrypt the data key at the following points:

- Elastic Transcoder decrypts your provided data key when it needs to use the data key to encrypt the output file or decrypt the input file.
- You decrypt a data key generated by Elastic Transcoder and use it to decrypt output files.

For more information, see [HLS Content Protection](#) in the *Amazon Elastic Transcoder Developer Guide*.

## Elastic Transcoder Encryption Context

An [encryption context](#) (p. 12) is a set of key–value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the

encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

Elastic Transcoder uses the same encryption context in all AWS KMS API requests to generate data keys, encrypt, and decrypt.

```
"service" : "elastictranscoder.amazonaws.com"
```

The encryption context is written to CloudTrail logs to help you understand how a given AWS KMS CMK was used. In the `requestParameters` field of a CloudTrail log file, the encryption context looks similar to the following:

```
"encryptionContext": {  
  "service" : "elastictranscoder.amazonaws.com"  
}
```

For more information about how to configure Elastic Transcoder jobs to use one of the supported encryption options, see [Data Encryption Options](#) in the *Amazon Elastic Transcoder Developer Guide*.

## How Amazon EMR Uses AWS KMS

When you use an [Amazon EMR](#) cluster, you can configure the cluster to encrypt data *at rest* before saving it to a persistent storage location. You can encrypt data at rest on the EMR File System (EMRFS), on the storage volumes of cluster nodes, or both. To encrypt data at rest, you can use a customer master key (CMK) in AWS KMS. The following topics explain how an Amazon EMR cluster uses a CMK to encrypt data at rest.

### Important

Amazon EMR supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt data at rest in an Amazon EMR cluster. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

Amazon EMR clusters also encrypt data *in transit*, which means the cluster encrypts data before sending it through the network. You cannot use a CMK to encrypt data in transit. For more information, see [In-Transit Data Encryption](#) in the *Amazon EMR Management Guide*.

For more information about all the encryption options available in Amazon EMR, see [Encryption Options](#) in the *Amazon EMR Management Guide*.

### Topics

- [Encrypting Data on the EMR File System \(EMRFS\) \(p. 249\)](#)
- [Encrypting Data on the Storage Volumes of Cluster Nodes \(p. 251\)](#)
- [Encryption Context \(p. 252\)](#)

## Encrypting Data on the EMR File System (EMRFS)

Amazon EMR clusters use two distributed files systems:

- The Hadoop Distributed File System (HDFS). HDFS encryption does not use a CMK in AWS KMS.
- The EMR File System (EMRFS). EMRFS is an implementation of HDFS that allows Amazon EMR clusters to store data in Amazon Simple Storage Service (Amazon S3). EMRFS supports four encryption

options, two of which use a CMK in AWS KMS. For more information about all four of the EMRFS encryption options, see [Encryption Options](#) in the *Amazon EMR Management Guide*.

The two EMRFS encryption options that use a CMK use the following encryption features offered by Amazon S3:

- [Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#). With SSE-KMS, the Amazon EMR cluster sends data to Amazon S3, and then Amazon S3 uses a CMK to encrypt the data before saving it to an S3 bucket. For more information about how this works, see [Process for Encrypting Data on EMRFS with SSE-KMS \(p. 250\)](#).
- [Client-Side Encryption with AWS KMS-Managed Keys \(CSE-KMS\)](#). With CSE-KMS, the Amazon EMR cluster uses a CMK to encrypt data before sending it to Amazon S3 for storage. For more information about how this works, see [Process for Encrypting Data on EMRFS with CSE-KMS \(p. 251\)](#).

When you configure an Amazon EMR cluster to encrypt data on EMRFS with SSE-KMS or CSE-KMS, you choose the CMK in AWS KMS that you want Amazon S3 or the Amazon EMR cluster to use. With SSE-KMS, you can choose the AWS managed CMK for Amazon S3 with the alias `aws/s3`, or a symmetric customer managed CMK that you create. With CSE-KMS, you must choose a symmetric customer managed CMK that you create. When you choose a customer managed CMK, you must ensure that your Amazon EMR cluster has permission to use the CMK. For more information, see [Using AWS KMS Customer Master Keys \(CMKs\) for Encryption](#) in the *Amazon EMR Management Guide*.

For both SSE-KMS and CSE-KMS, the CMK you choose is the master key in an [envelope encryption \(p. 11\)](#) workflow. The data is encrypted with a unique data encryption key (or *data key*), and this data key is encrypted under the CMK in AWS KMS. The encrypted data and an encrypted copy of its data key are stored together as a single encrypted object in an S3 bucket. For more information about how this works, see the following topics.

#### Topics

- [Process for Encrypting Data on EMRFS with SSE-KMS \(p. 250\)](#)
- [Process for Encrypting Data on EMRFS with CSE-KMS \(p. 251\)](#)

## Process for Encrypting Data on EMRFS with SSE-KMS

When you configure an Amazon EMR cluster to use SSE-KMS, the encryption process works like this:

1. The cluster sends data to Amazon S3 for storage in an S3 bucket.
2. Amazon S3 sends a [GenerateDataKey](#) request to AWS KMS, specifying the key ID of the CMK that you chose when you configured the cluster to use SSE-KMS. The request includes encryption context; for more information, see [Encryption Context \(p. 252\)](#).
3. AWS KMS generates a unique data encryption key (data key) and then sends two copies of this data key to Amazon S3. One copy is unencrypted (plaintext), and the other copy is encrypted under the CMK.
4. Amazon S3 uses the plaintext data key to encrypt the data that it received in step 1, and then removes the plaintext data key from memory as soon as possible after use.
5. Amazon S3 stores the encrypted data and the encrypted copy of the data key together as a single encrypted object in an S3 bucket.

The decryption process works like this:

1. The cluster requests an encrypted data object from an S3 bucket.

2. Amazon S3 extracts the encrypted data key from the S3 object, and then sends the encrypted data key to AWS KMS with a [Decrypt](#) request. The request includes an [encryption context](#) (p. 12).
3. AWS KMS decrypts the encrypted data key using the same CMK that was used to encrypt it, and then sends the decrypted (plaintext) data key to Amazon S3.
4. Amazon S3 uses the plaintext data key to decrypt the encrypted data, and then removes the plaintext data key from memory as soon as possible after use.
5. Amazon S3 sends the decrypted data to the cluster.

## Process for Encrypting Data on EMRFS with CSE-KMS

When you configure an Amazon EMR cluster to use CSE-KMS, the encryption process works like this:

1. When it's ready to store data in Amazon S3, the cluster sends a [GenerateDataKey](#) request to AWS KMS, specifying the key ID of the CMK that you chose when you configured the cluster to use CSE-KMS. The request includes encryption context; for more information, see [Encryption Context](#) (p. 252).
2. AWS KMS generates a unique data encryption key (data key) and then sends two copies of this data key to the cluster. One copy is unencrypted (plaintext), and the other copy is encrypted under the CMK.
3. The cluster uses the plaintext data key to encrypt the data, and then removes the plaintext data key from memory as soon as possible after use.
4. The cluster combines the encrypted data and the encrypted copy of the data key together into a single encrypted object.
5. The cluster sends the encrypted object to Amazon S3 for storage.

The decryption process works like this:

1. The cluster requests the encrypted data object from an S3 bucket.
2. Amazon S3 sends the encrypted object to the cluster.
3. The cluster extracts the encrypted data key from the encrypted object, and then sends the encrypted data key to AWS KMS with a [Decrypt](#) request. The request includes [encryption context](#) (p. 12).
4. AWS KMS decrypts the encrypted data key using the same CMK that was used to encrypt it, and then sends the decrypted (plaintext) data key to the cluster.
5. The cluster uses the plaintext data key to decrypt the encrypted data, and then removes the plaintext data key from memory as soon as possible after use.

## Encrypting Data on the Storage Volumes of Cluster Nodes

An Amazon EMR cluster is a collection of Amazon Elastic Compute Cloud (Amazon EC2) instances. Each instance in the cluster is called a *cluster node* or *node*. Each node can have two types of storage volumes: instance store volumes, and Amazon Elastic Block Store (Amazon EBS) volumes. You can configure the cluster to use [Linux Unified Key Setup \(LUKS\)](#) to encrypt both types of storage volumes on the nodes (but not the boot volume of each node). This is called *local disk encryption*.

When you enable local disk encryption for a cluster, you can choose to encrypt the LUKS master key with a CMK in AWS KMS. You must choose a custom CMK that you create; you cannot use an AWS managed CMK. When you choose a custom CMK, you must ensure that your Amazon EMR cluster has permission to use the CMK. For more information, see [Using AWS KMS Customer Master Keys \(CMKs\) for Encryption](#) in the *Amazon EMR Management Guide*.

When you enable local disk encryption using a CMK, the encryption process works like this:

1. When each cluster node launches, it sends a [GenerateDataKey](#) request to AWS KMS, specifying the key ID of the CMK that you chose when you enabled local disk encryption for the cluster.
2. AWS KMS generates a unique data encryption key (data key) and then sends two copies of this data key to the node. One copy is unencrypted (plaintext), and the other copy is encrypted under the CMK.
3. The node uses a base64-encoded version of the plaintext data key as the password that protects the LUKS master key. The node saves the encrypted copy of the data key on its boot volume.
4. If the node reboots, the rebooted node sends the encrypted data key to AWS KMS with a [Decrypt](#) request.
5. AWS KMS decrypts the encrypted data key using the same CMK that was used to encrypt it, and then sends the decrypted (plaintext) data key to the node.
6. The node uses the base64-encoded version of the plaintext data key as the password to unlock the LUKS master key.

## Encryption Context

Each AWS service that is integrated with AWS KMS can specify an [encryption context](#) (p. 12) when it uses AWS KMS to generate data keys or to encrypt or decrypt data. Encryption context is additional authenticated information that AWS KMS uses to check for data integrity. When a service specifies encryption context for an encryption operation, it must specify the same encryption context for the corresponding decryption operation or decryption will fail. Encryption context is also written to AWS CloudTrail log files, which can help you understand why a given CMK was used.

The following section explain the encryption context that is used in each Amazon EMR encryption scenario that uses a CMK.

### Encryption Context for EMRFS Encryption with SSE-KMS

With SSE-KMS, the Amazon EMR cluster sends data to Amazon S3, and then Amazon S3 uses a CMK to encrypt the data before saving it to an S3 bucket. In this case, Amazon S3 uses the Amazon Resource Name (ARN) of the S3 object as encryption context with each [GenerateDataKey](#) and [Decrypt](#) request that it sends to AWS KMS. The following example shows a JSON representation of the encryption context that Amazon S3 uses.

```
{ "aws:s3:arn" : "arn:aws:s3:::S3_bucket_name/S3_object_key" }
```

### Encryption Context for EMRFS Encryption with CSE-KMS

With CSE-KMS, the Amazon EMR cluster uses a CMK to encrypt data before sending it to Amazon S3 for storage. In this case, the cluster uses the Amazon Resource Name (ARN) of the CMK as encryption context with each [GenerateDataKey](#) and [Decrypt](#) request that it sends to AWS KMS. The following example shows a JSON representation of the encryption context that the cluster uses.

```
{ "kms_cmek_id" : "arn:aws:kms:us-east-2:111122223333:key/0987ab65-43cd-21ef-09ab-87654321cdef" }
```

### Encryption Context for Local Disk Encryption with LUKS

When an Amazon EMR cluster uses local disk encryption with LUKS, the cluster nodes do not specify encryption context with the [GenerateDataKey](#) and [Decrypt](#) requests that they send to AWS KMS.

# How Amazon Redshift Uses AWS KMS

This topic discusses how Amazon Redshift uses AWS KMS to encrypt data.

## Topics

- [Amazon Redshift Encryption \(p. 253\)](#)
- [Encryption Context \(p. 253\)](#)

## Amazon Redshift Encryption

An Amazon Redshift data warehouse is a collection of computing resources called nodes, which are organized into a group called a cluster. Each cluster runs an Amazon Redshift engine and contains one or more databases.

Amazon Redshift uses a four-tier, key-based architecture for encryption. The architecture consists of data encryption keys, a database key, a cluster key, and a master key.

Data encryption keys encrypt data blocks in the cluster. Each data block is assigned a randomly-generated AES-256 key. These keys are encrypted by using the database key for the cluster.

The database key encrypts data encryption keys in the cluster. The database key is a randomly-generated AES-256 key. It is stored on disk in a separate network from the Amazon Redshift cluster and passed to the cluster across a secure channel.

The cluster key encrypts the database key for the Amazon Redshift cluster. You can use AWS KMS, AWS CloudHSM, or an external hardware security module (HSM) to manage the cluster key. See the [Amazon Redshift Database Encryption](#) documentation for more details.

The master key encrypts the cluster key. You can use a AWS KMS [customer master key \(p. 2\)](#) (CMK) as the master key for Amazon Redshift. You can request encryption by checking the appropriate box in the Amazon Redshift console. You can specify a [customer managed CMK \(p. 3\)](#) to use by choosing one from the list that appears below the encryption box. If you do not specify a customer managed CMK, Amazon Redshift uses the [AWS managed CMK \(p. 4\)](#) for Amazon Redshift under your account.

### Important

Amazon Redshift supports only symmetric CMKs. You cannot use an asymmetric CMK as the master key in an Amazon Redshift encryption workflow. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

## Encryption Context

Each service that is integrated with AWS KMS specifies an [encryption context \(p. 12\)](#) when requesting data keys, encrypting, and decrypting. The encryption context is [additional authenticated data](#) (AAD) that AWS KMS uses to check for data integrity. That is, when an encryption context is specified for an encryption operation, the service also specifies it for the decryption operation or decryption will not succeed. Amazon Redshift uses the cluster ID and the creation time for the encryption context. In the `requestParameters` field of a CloudTrail log file, the encryption context will look similar to this.

```
"encryptionContext": {  
  "aws:redshift:arn": "arn:aws:redshift:region:account_ID:cluster:cluster_name",  
  "aws:redshift:createtime": "20150206T1832Z"  
},
```

You can search on the cluster name in your CloudTrail logs to understand what operations were performed by using a customer master key (CMK). The operations include cluster encryption, cluster decryption, and generating data keys.

## How Amazon Relational Database Service (Amazon RDS) Uses AWS KMS

You can use the [Amazon Relational Database Service \(Amazon RDS\)](#) to set up, operate, and scale a relational database in the cloud. Optionally, you can choose to encrypt the data stored on your Amazon RDS [DB instance](#) under a [customer master key \(p. 2\)](#) (CMK) in AWS KMS. To learn how to encrypt your Amazon RDS resources under an AWS KMS CMK, see [Encrypting Amazon RDS Resources](#) in the *Amazon RDS User Guide*.

### Important

Amazon RDS supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt data in an Amazon RDS database. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

Amazon RDS builds on [Amazon Elastic Block Store \(Amazon EBS\) encryption](#) to provide full disk encryption for database volumes. For more information about how Amazon EBS uses AWS KMS to encrypt volumes, see [How Amazon Elastic Block Store \(Amazon EBS\) Uses AWS KMS \(p. 243\)](#).

When you create an encrypted DB instance with Amazon RDS, Amazon RDS creates an encrypted EBS volume on your behalf to store the database. Data stored at rest on the volume, database snapshots, automated backups, and read replicas are all encrypted under the KMS CMK that you specified when you created the DB instance.

## Amazon RDS Encryption Context

When Amazon RDS uses your KMS CMK, or when Amazon EBS uses it on behalf of Amazon RDS, the service specifies an [encryption context \(p. 12\)](#). The encryption context is [additional authenticated data \(AAD\)](#) that AWS KMS uses to ensure data integrity. When an encryption context is specified for an encryption operation, the service must specify the same encryption context for the decryption operation. Otherwise, decryption fails. The encryption context is also written to your [AWS CloudTrail](#) logs to help you understand why a given CMK was used. Your CloudTrail logs might contain many entries describing the use of a CMK, but the encryption context in each log entry can help you determine the reason for that particular use.

At minimum, Amazon RDS always uses the DB instance ID for the encryption context, as in the following JSON-formatted example:

```
{ "aws:rds:db-id": "db-CQYSMDPBRZ7BPMH7Y3RTDG5QY" }
```

This encryption context can help you identify the DB instance for which your CMK was used.

When your CMK is used for a specific DB instance and a specific EBS volume, both the DB instance ID and the EBS volume ID are used for the encryption context, as in the following JSON-formatted example:

```
{
  "aws:rds:db-id": "db-BRG7VYS3SVIFQW7234EJQOM5RQ",
  "aws:ebs:id": "vol-ad8c6542"
}
```

## How AWS Secrets Manager Uses AWS KMS

[AWS Secrets Manager](#) is an AWS service that encrypts and stores your secrets, and transparently decrypts and returns them to you in plaintext. It's designed especially to store application secrets, such as login credentials, that change periodically and should not be hard-coded or stored in plaintext in the application. In place of hard-coded credentials or table lookups, your application calls Secrets Manager.

Secrets Manager also supports features that periodically rotate the secrets associated with commonly used databases. It always encrypts newly rotated secrets before they are stored.

Secrets Manager integrates with AWS Key Management Service (AWS KMS) to encrypt every version of every secret with a unique [data encryption key \(p. 4\)](#) that is protected by an AWS KMS [customer master key \(p. 2\)](#) (CMK). This integration protects your secrets under encryption keys that never leave AWS KMS unencrypted. It also enables you to set custom permissions on the master key and audit the operations that generate, encrypt, and decrypt the data keys that protect your secrets.

### Topics

- [Protecting the Secret Value \(p. 255\)](#)
- [Encrypting and Decrypting Secrets \(p. 255\)](#)
- [Using Your AWS KMS CMK \(p. 257\)](#)
- [Authorizing Use of the CMK \(p. 258\)](#)
- [Secrets Manager Encryption Context \(p. 259\)](#)
- [Monitoring Secrets Manager Interaction with AWS KMS \(p. 260\)](#)

## Protecting the Secret Value

To protect a secret, Secrets Manager encrypts the *secret value* in a secret.

In Secrets Manager, a [secret](#) consists of a *secret value*, also known as *protected secret text* or *encrypted secret data*, and related metadata and version information. The secret value can be any string or binary data of up to 10,240 bytes, but it is typically a collection of name-value pairs that comprise the login information for a server or database.

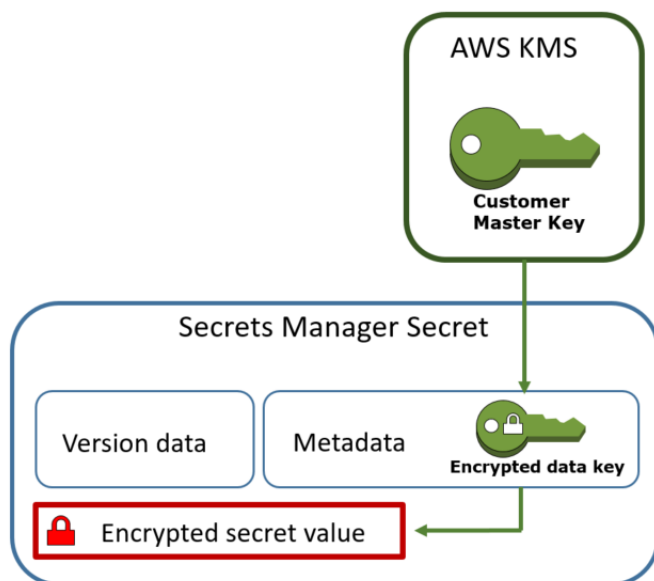

Secrets Manager always encrypts the entire secret value before it stores the secret. It decrypts the secret value transparently whenever you get or change the secret value. There is no option to enable or disable encryption. To encrypt and decrypt the secret value, Secrets Manager uses AWS KMS.

## Encrypting and Decrypting Secrets

To protect secrets, Secrets Manager uses [envelope encryption \(p. 11\)](#) with AWS KMS [customer master keys \(p. 2\)](#) (CMKs) and [data keys \(p. 4\)](#).

Secrets Manager uses a unique data key to protect each secret value. Whenever the secret value in a secret changes, Secrets Manager generates a new data key to protect it. The data key is encrypted under an AWS KMS CMK and stored in the metadata of the secret, as shown in the following image. To decrypt the secret, Secrets Manager must first decrypt the encrypted data key using the CMK in AWS KMS.

## An AWS KMS CMK for Each Secret

Each secret is associated with an AWS managed or customer managed [customer master key \(p. 2\)](#) (CMK). Customer managed CMKs allow authorized users to [control access \(p. 46\)](#) to the CMK through policies and grants, manage [automatic rotation \(p. 142\)](#), and use [imported key material \(p. 147\)](#).

### Important

Secrets Manager supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your secrets. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

When you create a new secret, you can specify any symmetric customer managed CMK in the account and region, or the AWS managed CMK for Secrets Manager, `aws/secretsmanager`. If you do not specify a CMK, or you select the console default value, **DefaultEncryptionKey**, Secrets Manager creates the `aws/secretsmanager` CMK, if it does not exist, and associates it with the secret. You can use the same CMK or different CMKs for each secret in your account.

You can change the CMK for a secret at any time, either in the Secrets Manager console, or by using the [UpdateSecret](#) operation. When you change the CMK, Secrets Manager does not re-encrypt the existing secret value under the new CMK. However, the next time that the secret value changes, Secrets Manager encrypts it under the new CMK.

To find the CMK that is associated with a secret, use the [ListSecrets](#) or [DescribeSecret](#) operations. When the secret is associated with the AWS managed CMK for Secrets Manager (`aws/secretsmanager`), these operations do not return a CMK identifier.

Secrets Manager does not use the CMK to encrypt the secret value directly. Instead, it uses the CMK to generate and encrypt a unique data key, and it uses the data key to encrypt the secret value.

## A Unique Data Key for Each Secret Value

Every time that you create or change the secret value in a secret, Secrets Manager uses the CMK that is associated with the secret to generate and encrypt a unique 256-bit Advanced Encryption Standard (AES) symmetric [data key \(p. 4\)](#). Secrets Manager uses the plaintext data key to encrypt the secret value outside of AWS KMS, and then removes it from memory. It stores the encrypted copy of the data key in the metadata of the secret.

The secret value is ultimately protected by the CMK, which never leaves AWS KMS unencrypted. Before Secrets Manager can decrypt the secret, it must ask AWS KMS to decrypt the encrypted data key.

## Encrypting a Secret Value

To encrypt the secret value in a secret, Secrets Manager uses the following process.

1. Secrets Manager calls the AWS KMS [GenerateDataKey](#) operation with the ID of the CMK for the secret and a request for a 256-bit AES symmetric key. AWS KMS returns a plaintext data key and a copy of that data key encrypted under the CMK.
2. Secrets Manager uses the plaintext data key and the Advanced Encryption Standard (AES) algorithm to encrypt the secret value outside of AWS KMS. It removes the plaintext key from memory as soon as possible after using it.
3. Secrets Manager stores the encrypted data key in the metadata of the secret so it is available to decrypt the secret value. However, none of the Secrets Manager APIs return the encrypted secret or the encrypted data key.

## Decrypting a Secret Value

To decrypt an encrypted secret value, Secrets Manager must first decrypt the encrypted data key. Because the data key is encrypted under the CMK for the secret in AWS KMS, Secrets Manager must make a request to AWS KMS.

To decrypt an encrypted secret value:

1. Secrets Manager calls the AWS KMS [Decrypt](#) operation and passes in the encrypted data key.
2. AWS KMS uses the CMK for the secret to decrypt the data key. It returns the plaintext data key.
3. Secrets Manager uses the plaintext data key to decrypt the secret value. Then it removes the data key from memory as soon as possible.

## Using Your AWS KMS CMK

Secrets Manager uses the [customer master key \(p. 2\)](#) (CMK) that is associated with a secret to generate a data key for each secret value. It also uses the CMK to decrypt that data key when it needs to decrypt the encrypted secret value. You can track the requests and responses in AWS CloudTrail events, [Amazon CloudWatch Logs \(p. 260\)](#), and audit trails.

The following Secrets Manager operations trigger a request to use your AWS KMS CMK.

### GenerateDataKey

Secrets Manager calls the AWS KMS [GenerateDataKey](#) operation in response to the following Secrets Manager operations.

- [CreateSecret](#) – If the new secret includes a secret value, Secrets Manager requests a new data key to encrypt it.
- [PutSecretValue](#)– Secrets Manager requests a new data key to encrypt the specified secret value.
- [UpdateSecret](#) – If the update changes the secret value, Secrets Manager requests a new data key to encrypt the new secret value.

#### Note

The [RotateSecret](#) operation does not call [GenerateDataKey](#), because it does not change the secret value. However, if the Lambda function that [RotateSecret](#) invokes changes

the secret value, its call to the `PutSecretValue` operation triggers a `GenerateDataKey` request.

### Decrypt

To decrypt an encrypted secret value, Secrets Manager calls the AWS KMS [Decrypt](#) operation to decrypt the encrypted data key in the secret. Then, it uses the plaintext data key to decrypt the encrypted secret value.

Secrets Manager calls the [Decrypt](#) operation in response to the following Secrets Manager operations.

- [GetSecretValue](#) – Secrets Manager decrypts the secret value before returning it to the caller.
- [PutSecretValue](#) and [UpdateSecret](#) – Most `PutSecretValue` and `UpdateSecret` requests do not trigger a `Decrypt` operation. However, when a `PutSecretValue` or `UpdateSecret` request attempts to change the secret value in an existing version of a secret, Secrets Manager decrypts the existing secret value and compares it to the secret value in the request to confirm that they are the same. This action ensures that Secrets Manager operations are idempotent.

### Validating Access to the CMK

When you establish or change the CMK that is associated with secret, Secrets Manager calls the `GenerateDataKey` and `Decrypt` operations with the specified CMK. These calls confirm that the caller has permission to use the CMK for these operation. Secrets Manager discards the results of these operations; it does not use them in any cryptographic operation.

You can identify these validation calls because the value of the `SecretVersionId` key [encryption context](#) (p. 259) in these requests is `RequestToValidateKeyAccess`.

#### Note

In the past, Secrets Manager validation calls did not include an encryption context. You might find calls with no encryption context in older AWS CloudTrail logs.

## Authorizing Use of the CMK

When Secrets Manager uses a [customer master key](#) (p. 2) (CMK) in cryptographic operations, it acts on behalf of the user who is creating or changing the secret value in the secret.

To use the AWS KMS customer master key (CMK) for a secret on your behalf, the user must have the following permissions. You can specify these required permissions in an IAM policy or key policy.

- `kms:GenerateDataKey`
- `kms:Decrypt`

To allow the CMK to be used only for requests that originate in Secrets Manager, you can use the [kms:ViaService condition key](#) (p. 111) with the `secretsmanager.<region>.amazonaws.com` value.

You can also use the keys or values in the [encryption context](#) (p. 259) as a condition for using the CMK for cryptographic operations. For example, you can use a [string condition operator](#) in an IAM or key policy document, or use a [grant constraint](#) in a grant.

## Key Policy of the AWS Managed CMK

The key policy for the AWS managed CMK for Secrets Manager gives users permission to use the CMK for specified operations only when Secrets Manager makes the request on the user's behalf. The key policy does not allow any user to use the CMK directly.

This key policy, like the policies of all [AWS managed keys \(p. 2\)](#), is established by the service. You cannot change the key policy, but you can view it at any time. For details, see [Viewing a Key Policy \(p. 61\)](#).

The policy statements in the key policy have the following effect:

- Allow users in the account to use the CMK for cryptographic operations only when the request comes from Secrets Manager on their behalf. The `kms:ViaService` condition key enforces this restriction.
- Allows the AWS account to create IAM policies that allow users to view CMK properties and revoke grants.
- Although Secrets Manager does not use grants to gain access to the CMK, the policy also allows Secrets Manager to [create grants \(p. 115\)](#) for the CMK on the user's behalf and allows the account to [revoke any grant](#) that allows Secrets Manager to use the CMK. These are standard elements of policy document for an AWS managed CMK.

The following is a key policy for an example AWS managed CMK for Secrets Manager.

```
{
  "Version" : "2012-10-17",
  "Id" : "auto-secretsmanager-1",
  "Statement" : [ {
    "Sid" : "Allow access through AWS Secrets Manager for all principals in the account
    that are authorized to use AWS S
    ecrets Manager",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "*"
    },
    "Action" : [ "kms:Encrypt", "kms:Decrypt", "kms:ReEncrypt*", "kms:GenerateDataKey*",
    "kms:CreateGrant", "kms:DescribeKey" ],
    "Resource" : "*",
    "Condition" : {
      "StringEquals" : {
        "kms:ViaService" : "secretsmanager.us-west-2.amazonaws.com",
        "kms:CallerAccount" : "111122223333"
      }
    }
  }, {
    "Sid" : "Allow direct access to key metadata to the account",
    "Effect" : "Allow",
    "Principal" : {
      "AWS" : "arn:aws:iam::111122223333:root"
    },
    "Action" : [ "kms:Describe*", "kms:Get*", "kms:List*", "kms:RevokeGrant" ],
    "Resource" : "*"
  } ]
}
```

## Secrets Manager Encryption Context

An [encryption context \(p. 12\)](#) is a set of key–value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

In its [GenerateDataKey](#) and [Decrypt](#) requests to AWS KMS, Secrets Manager uses an encryption context with two name–value pairs that identify the secret and its version, as shown in the following example. The names do not vary, but combined encryption context values will be different for each secret value.

```
"encryptionContext": {
```

```
"SecretARN": "arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-a1b2c3",  
"SecretVersionId": "EXAMPLE1-90ab-cdef-fedc-ba987SECRET1"  
}
```

You can use the encryption context to identify these cryptographic operation in audit records and logs, such as [AWS CloudTrail](#) and Amazon CloudWatch Logs, and as a condition for authorization in policies and grants.

The Secrets Manager encryption context consists of two name-value pairs.

- **SecretARN** – The first name-value pair identifies the secret. The key is `SecretARN`. The value is the Amazon Resource Name (ARN) of the secret.

```
"SecretARN": "ARN of an Secrets Manager secret"
```

For example, if the ARN of the secret is `arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-a1b2c3`, the encryption context would include the following pair.

```
"SecretARN": "arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-a1b2c3"
```

- **SecretVersionId** – The second name-value pair identifies the version of the secret. The key is `SecretVersionId`. The value is the version ID.

```
"SecretVersionId": "<version-id>"
```

For example, if the version ID of the secret is `EXAMPLE1-90ab-cdef-fedc-ba987SECRET1`, the encryption context would include the following pair.

```
"SecretVersionId": "EXAMPLE1-90ab-cdef-fedc-ba987SECRET1"
```

When you establish or change the CMK for a secret, Secrets Manager sends [GenerateDataKey](#) and [Decrypt](#) requests to AWS KMS to validate that the caller has permission to use the CMK for these operations. It discards the responses; it does not use them on the secret value.

In these validation requests, the value of the `SecretARN` is the actual ARN of the secret, but the `SecretVersionId` value is `RequestToValidateKeyAccess`, as shown in the following example encryption context. This special value helps you to identify validation requests in logs and audit trails.

```
"encryptionContext": {  
  "SecretARN": "arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-a1b2c3",  
  "SecretVersionId": "RequestToValidateKeyAccess"  
}
```

#### Note

In the past, Secrets Manager validation requests did not include an encryption context. You might find calls with no encryption context in older AWS CloudTrail logs.

## Monitoring Secrets Manager Interaction with AWS KMS

You can use AWS CloudTrail and Amazon CloudWatch Logs to track the requests that Secrets Manager sends to AWS KMS on your behalf.

## GenerateDataKey

When you [create or change \(p. 257\)](#) the secret value in a secret, Secrets Manager sends a [GenerateDataKey](#) request to AWS KMS that specifies the CMK for the secret.

The event that records the GenerateDataKey operation is similar to the following example event. The request is invoked by `secretsmanager.amazonaws.com`. The parameters include the Amazon Resource Name (ARN) of the CMK for the secret, a key specifier that requires a 256-bit key, and the [encryption context \(p. 259\)](#) that identifies the secret and version.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AROAIQDTESTANDEXAMPLE:user01",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admin/user01",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2018-05-31T23:23:41Z"
      }
    }
  },
  "invokedBy": "secretsmanager.amazonaws.com"
},
{
  "eventTime": "2018-05-31T23:23:41Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "GenerateDataKey",
  "awsRegion": "us-west-2",
  "sourceIPAddress": "secretsmanager.amazonaws.com",
  "userAgent": "secretsmanager.amazonaws.com",
  "requestParameters": {
    "keyId": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
    "keySpec": "AES_256",
    "encryptionContext": {
      "SecretARN": "arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-a1b2c3",
      "SecretVersionId": "EXAMPLE1-90ab-cdef-fedc-ba987SECRET1"
    }
  },
  "responseElements": null,
  "requestID": "a7d4dd6f-6529-11e8-9881-67744a270888",
  "eventID": "af7476b6-62d7-42c2-bc02-5ce86c21ed36",
  "readOnly": true,
  "resources": [
    {
      "ARN": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "accountId": "111122223333",
      "type": "AWS::KMS::Key"
    }
  ],
  "eventType": "AwsApiCall",
  "recipientAccountId": "111122223333"
}
```

## Decrypt

Whenever you [get or change \(p. 257\)](#) the secret value of a secret, Secrets Manager sends a [Decrypt](#) request to AWS KMS to decrypt the encrypted data key.

The event that records the `Decrypt` operation is similar to the following example event. The user is the principal in your AWS account who is accessing the table. The parameters include the encrypted table key (as a ciphertext blob) and the [encryption context](#) (p. 259) that identifies the table and the AWS account. AWS KMS derives the ID of the CMK from the ciphertext.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "IAMUser",
    "principalId": "AROAIQDTESTANDEXAMPLE:user01",
    "arn": "arn:aws:sts::111122223333:assumed-role/Admin/user01",
    "accountId": "111122223333",
    "accessKeyId": "AKIAIOSFODNN7EXAMPLE",
    "sessionContext": {
      "attributes": {
        "mfaAuthenticated": "false",
        "creationDate": "2018-05-31T23:36:09Z"
      }
    }
  },
  "invokedBy": "secretsmanager.amazonaws.com"
},
{
  "eventTime": "2018-05-31T23:36:09Z",
  "eventSource": "kms.amazonaws.com",

  "userAgent": "secretsmanager.amazonaws.com",
  "requestParameters": {
    "encryptionContext": {
      "SecretARN": "arn:aws:secretsmanager:us-west-2:111122223333:secret:test-secret-alb2c3",
      "SecretVersionId": "EXAMPLE1-90ab-cdef-fedc-ba987SECRET1"
    }
  },
  "responseElements": null,
  "requestID": "658c6a08-652b-11e8-a6d4-ffee2046048a",
  "eventID": "f333ec5c-7fc1-46b1-b985-cbda13719611",
  "readOnly": true,
  "resources": [
    {
      "ARN": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "accountId": "111122223333",
      "type": "AWS::KMS::Key"
    }
  ],
  "eventType": "AwsApiCall",
  "recipientAccountId": "111122223333"
}
```

## How Amazon Simple Email Service (Amazon SES) Uses AWS KMS

You can use Amazon Simple Email Service (Amazon SES) to receive email, and (optionally) to encrypt the received email messages before storing them in an Amazon Simple Storage Service (Amazon S3) bucket that you choose. When you configure Amazon SES to encrypt email messages, you must choose the AWS KMS [customer master key](#) (p. 2) (CMK) under which Amazon SES encrypts the messages. You can choose the [AWS managed CMK](#) (p. 4) for Amazon SES (its alias is **aws/ses**), or you can choose a symmetric [customer managed CMK](#) (p. 3) that you created in AWS KMS.

### Important

Amazon SES supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your Amazon SES email messages. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

For more information about receiving email using Amazon SES, go to [Receiving Email with Amazon SES](#) in the *Amazon Simple Email Service Developer Guide*.

### Topics

- [Overview of Amazon SES Encryption Using AWS KMS \(p. 263\)](#)
- [Amazon SES Encryption Context \(p. 263\)](#)
- [Giving Amazon SES Permission to Use Your AWS KMS Customer Master Key \(CMK\) \(p. 264\)](#)
- [Getting and Decrypting Email Messages \(p. 264\)](#)

## Overview of Amazon SES Encryption Using AWS KMS

When you configure Amazon SES to receive email and encrypt the email messages before saving them to your S3 bucket, the process works like this:

1. You [create a receipt rule](#) for Amazon SES, specifying the S3 action, an S3 bucket for storage, and a KMS customer master key (CMK) for encryption.
2. Amazon SES receives an email message that matches your receipt rule.
3. Amazon SES requests a unique data key encrypted with the KMS CMK that you specified in the applicable receipt rule.
4. AWS KMS creates a new data key, encrypts it with the specified CMK, and then sends the encrypted and plaintext copies of the data key to Amazon SES.
5. Amazon SES uses the plaintext data key to encrypt the email message and then removes the plaintext data key from memory as soon as possible after use.
6. Amazon SES puts the encrypted email message and the encrypted data key in the specified S3 bucket. The encrypted data key is stored as metadata with the encrypted email message.

To accomplish [Step 3 \(p. 263\)](#) through [Step 6 \(p. 263\)](#), Amazon SES uses the AWS–provided Amazon S3 encryption client. Use the same client to retrieve your encrypted email messages from Amazon S3 and decrypt them. For more information, see [Getting and Decrypting Email Messages \(p. 264\)](#).

## Amazon SES Encryption Context

When Amazon SES requests a data key to encrypt your received email messages ([Step 3 \(p. 263\)](#) in the [Overview of Amazon SES Encryption Using AWS KMS \(p. 263\)](#)), it includes an [encryption context \(p. 12\)](#) in the request. The encryption context provides [additional authenticated data \(AAD\)](#) that AWS KMS uses to ensure data integrity. The encryption context is also written to your AWS CloudTrail log files, which can help you understand why a given customer master key (CMK) was used. Amazon SES uses the following encryption context:

- The ID of the AWS account in which you've configured Amazon SES to receive email messages
- The rule name of the Amazon SES receipt rule that invoked the S3 action on the email message
- The Amazon SES message ID for the email message

The following example shows a JSON representation of the encryption context that Amazon SES uses:

```
{
```

```
"aws:ses:source-account": "111122223333",  
"aws:ses:rule-name": "example-receipt-rule-name",  
"aws:ses:message-id": "d6iitobk75ur44p8kdnp7g2n800"  
}
```

## Giving Amazon SES Permission to Use Your AWS KMS Customer Master Key (CMK)

You can use the default customer master key (CMK) in your account for Amazon SES with the alias **aws/ses**, or you can use a custom CMK you create. If you use the default CMK for Amazon SES, you don't need to perform any steps to give Amazon SES permission to use it. However, to specify a custom CMK when you [add the S3 action](#) to your Amazon SES receipt rule, you must ensure that Amazon SES has permission to use the CMK to encrypt your email messages. To give Amazon SES permission to use your custom CMK, add the following statement to your CMK's [key policy](#) (p. 50):

```
{  
  "Sid": "Allow SES to encrypt messages using this master key",  
  "Effect": "Allow",  
  "Principal": {"Service": "ses.amazonaws.com"},  
  "Action": [  
    "kms:Encrypt",  
    "kms:GenerateDataKey*"  
  ],  
  "Resource": "*",  
  "Condition": {  
    "Null": {  
      "kms:EncryptionContext:aws:ses:rule-name": false,  
      "kms:EncryptionContext:aws:ses:message-id": false  
    },  
    "StringEquals": {"kms:EncryptionContext:aws:ses:source-account": "ACCOUNT-ID-WITHOUT-HYPHENS" }  
  }  
}
```

Replace **ACCOUNT-ID-WITHOUT-HYPHENS** with the 12-digit ID of the AWS account in which you've configured Amazon SES to receive email messages. This policy statement allows Amazon SES to encrypt data with this CMK only under these conditions:

- Amazon SES must specify `aws:ses:rule-name` and `aws:ses:message-id` in the `EncryptionContext` of their AWS KMS API requests.
- Amazon SES must specify `aws:ses:source-account` in the `EncryptionContext` of their AWS KMS API requests, and the value for `aws:ses:source-account` must match the AWS account ID specified in the key policy.

For more information about the encryption context that Amazon SES uses when encrypting your email messages, see [Amazon SES Encryption Context](#) (p. 263). For general information about how AWS KMS uses the encryption context, see [encryption context](#) (p. 12).

## Getting and Decrypting Email Messages

Amazon SES does not have permission to decrypt your encrypted email messages and cannot decrypt them for you. You must write code to get your email messages from Amazon S3 and decrypt them. To make this easier, use the Amazon S3 encryption client. The following AWS SDKs include the Amazon S3 encryption client:

- [AWS SDK for Java](#) – See [AmazonS3EncryptionClient](#) in the *AWS SDK for Java API Reference*.

- [AWS SDK for Ruby](#) – See [Aws::S3::Encryption::Client](#) in the *AWS SDK for Ruby API Reference*.
- [AWS SDK for .NET](#) – See [AmazonS3EncryptionClient](#) in the *AWS SDK for .NET API Reference*.
- [AWS SDK for Go](#) – See [s3crypto](#) in the *AWS SDK for Go API Reference*.

The Amazon S3 encryption client simplifies the work of constructing the necessary requests to Amazon S3 to retrieve the encrypted email message and to AWS KMS to decrypt the message's encrypted data key, and of decrypting the email message. For example, to successfully decrypt the encrypted data key you must pass the same encryption context that Amazon SES passed when requesting the data key from AWS KMS ([Step 3 \(p. 263\)](#) in the [Overview of Amazon SES Encryption Using AWS KMS \(p. 263\)](#)). The Amazon S3 encryption client handles this, and much of the other work, for you.

For sample code that uses the Amazon S3 encryption client in the AWS SDK for Java to do client-side decryption, see the following:

- [Example: Client-Side Encryption \(Option 1: Using an AWS KMS–Managed Customer Master Key \(AWS SDK for Java\)\)](#) in the *Amazon Simple Storage Service Developer Guide*.
- [Amazon S3 Encryption with AWS Key Management Service](#) on the AWS Developer Blog.

## How Amazon Simple Storage Service (Amazon S3) Uses AWS KMS

This topic discusses how to protect data at rest within Amazon S3 data centers by using AWS KMS. There are two ways to use AWS KMS with Amazon S3. You can use server-side encryption to protect your data with a master key or you can use an AWS KMS customer master key (CMK) with the Amazon S3 Encryption Client to protect your data on the client side.

### Topics

- [Server-Side Encryption: Using SSE-KMS \(p. 265\)](#)
- [Using the Amazon S3 Encryption Client \(p. 266\)](#)
- [Encryption Context \(p. 266\)](#)

## Server-Side Encryption: Using SSE-KMS

You can protect data at rest in Amazon S3 by using three different modes of server-side encryption: SSE-S3, SSE-C, or SSE-KMS.

- SSE-S3 requires that Amazon S3 manage the data and master encryption keys. For more information about SSE-S3, see [Protecting Data Using Server-Side Encryption with Amazon S3–Managed Encryption Keys \(SSE-S3\)](#).
- SSE-C requires that you manage the encryption key. For more information about SSE-C, see [Protecting Data Using Server-Side Encryption with Customer-Provided Encryption Keys \(SSE-C\)](#).
- SSE-KMS requires that AWS manage the data key but you manage the [customer master key \(p. 2\)](#) (CMK) in AWS KMS.

The remainder of this topic discusses how to protect data by using server-side encryption with AWS KMS-managed keys (SSE-KMS).

You can request encryption and select a CMK by using the Amazon S3 console or API. In the console, check the appropriate box to perform encryption and select your CMK from the list. For the Amazon S3

API, specify encryption and choose your CMK by setting the appropriate headers in a GET or PUT request. For more information, see [Protecting Data Using Server-Side Encryption with AWS KMS-Managed Keys \(SSE-KMS\)](#).

### Important

Amazon S3 supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your data in Amazon S3. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

You can choose a [customer managed CMK \(p. 3\)](#) or the [AWS managed CMK \(p. 4\)](#) for Amazon S3 in your account. If you choose to encrypt your data, AWS KMS and Amazon S3 perform the following actions:

- Amazon S3 requests a plaintext data key and a copy of the key encrypted under the specified CMK.
- AWS KMS creates a data key, encrypts it by using the master key, and sends both the plaintext data key and the encrypted data key to Amazon S3.
- Amazon S3 encrypts the data using the data key and removes the plaintext key from memory as soon as possible after use.
- Amazon S3 stores the encrypted data key as metadata with the encrypted data.

Amazon S3 and AWS KMS perform the following actions when you request that your data be decrypted.

- Amazon S3 sends the encrypted data key to AWS KMS.
- AWS KMS decrypts the key by using the appropriate master key and sends the plaintext key back to Amazon S3.
- Amazon S3 decrypts the ciphertext and removes the plaintext data key from memory as soon as possible.

## Using the Amazon S3 Encryption Client

You can use the [Amazon S3 Encryption Client](#) in the AWS SDK in your own application to encrypt objects and upload them to Amazon S3. This method allows you to encrypt your data locally to ensure its security as it passes to the Amazon S3 service. The Amazon S3 service receives your encrypted data; it does not play a role in encrypting or decrypting it.

The Amazon S3 Encryption Client encrypts the object by using envelope encryption. The client calls AWS KMS as a part of the encryption call you make when you pass your data to the client. AWS KMS verifies that you are authorized to use the [customer master key \(p. 2\)](#) (CMK) that you and, if so, returns a new plaintext data key and the data key encrypted under the CMK. The Amazon S3 Encryption Client encrypts the data by using the plaintext key and then deletes the key from memory. The encrypted data key is sent to Amazon S3 to store alongside your encrypted data.

## Encryption Context

Each service that is integrated with AWS KMS specifies an [encryption context \(p. 12\)](#) when requesting data keys, encrypting, and decrypting. The encryption context is [additional authenticated data \(AAD\)](#) that AWS KMS uses to check for data integrity. When an encryption context is specified for an encryption operation, Amazon S3 specifies the same encryption the decryption operation. Otherwise, the decryption fails. If you are using SSE-KMS or the Amazon S3 encryption client to perform encryption, Amazon S3 uses the bucket path as the encryption context. In the `requestParameters` field of a CloudTrail log file, the encryption context will look similar to this.

```
"encryptionContext": {  
  "aws:s3:arn": "arn:aws:s3:::bucket_name/file_name"
```

```
},
```

## How AWS Systems Manager Parameter Store Uses AWS KMS

With AWS Systems Manager Parameter Store, you can create [secure string parameters](#), which are parameters that have a plaintext parameter name and an encrypted parameter value. Parameter Store uses AWS KMS to encrypt and decrypt the parameter values of secure string parameters.

With [Parameter Store](#) you can create, store, and manage data as parameters with values. You can create a parameter in Parameter Store and use it in multiple applications and services subject to policies and permissions that you design. When you need to change a parameter value, you change one instance, rather than managing error-prone changes to numerous sources. Parameter Store supports a hierarchical structure for parameter names, so you can qualify a parameter for specific uses.

To manage sensitive data, you can create secure string parameters. Parameter Store uses AWS KMS customer master keys (CMKs) to encrypt the parameter values of secure string parameters when you create or change them. It also uses CMKs to decrypt the parameter values when you access them. You can use the [AWS managed CMK \(p. 4\)](#) that Parameter Store creates for your account or specify your own [customer managed CMK \(p. 3\)](#).

### Important

Parameter Store supports only [symmetric CMKs \(p. 130\)](#). You cannot use an [asymmetric CMK \(p. 130\)](#) to encrypt your parameters. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

Parameter Store supports two tiers of secure string parameters: *standard* and *advanced*. Standard parameters, which cannot exceed 4096 bytes, are encrypted and decrypted directly under the CMK that you specify. To encrypt and decrypt advanced secure string parameters, Parameter Store uses envelope encryption with the [AWS Encryption SDK](#). You can convert a standard secure string parameter to an advanced parameter, but you cannot convert an advanced parameter to a standard one. For more information about the difference between standard and advanced secure string parameters, see [About Systems Manager Advanced Parameters](#) in the AWS Systems Manager User Guide.

### Topics

- [Protecting Standard Secure String Parameters \(p. 267\)](#)
- [Protecting Advanced Secure String Parameters \(p. 269\)](#)
- [Setting Permissions to Encrypt and Decrypt Parameter Values \(p. 272\)](#)
- [Parameter Store Encryption Context \(p. 274\)](#)
- [Troubleshooting CMK Issues in Parameter Store \(p. 275\)](#)

## Protecting Standard Secure String Parameters

Parameter Store does not perform any cryptographic operations. Instead, it relies on AWS KMS to encrypt and decrypt secure string parameter values. When you create or change a standard secure string parameter value, Parameter Store calls the AWS KMS [Encrypt](#) operation. This operation uses a symmetric AWS KMS CMK directly to encrypt the parameter value instead of using the CMK to generate a [data key \(p. 4\)](#).

You can select the CMK that Parameter Store uses to encrypt the parameter value. If you do not specify a CMK, Parameter Store uses the AWS managed CMK that Systems Manager automatically creates in your account. This CMK has the `aws/ssm` alias.

To view the default `aws/ssm` CMK for your account, use the [DescribeKey](#) operation in the AWS KMS API. The following example uses the `describe-key` command in the AWS Command Line Interface (AWS CLI) with the `aws/ssm` alias name.

```
aws kms describe-key --key-id alias/aws/ssm
```

To create a standard secure string parameter, use the [PutParameter](#) operation in the Systems Manager API. Omit the `Tier` parameter or specify a value of `Standard`, which is the default. Include a `Type` parameter with a value of `SecureString`. To specify an AWS KMS CMK, use the `KeyId` parameter. The default is the AWS managed CMK for your account, `aws/ssm`.

Parameter Store then calls the AWS KMS `Encrypt` operation with the CMK and the plaintext parameter value. AWS KMS returns the encrypted parameter value, which Parameter Store stores with the parameter name.

The following example uses the Systems Manager [put-parameter](#) command and its `--type` parameter in the AWS CLI to create a secure string parameter. Because the command omits the optional `--tier` and `--key-id` parameters, Parameter Store creates a standard secure string parameter and encrypts it under the AWS managed CMK.

```
aws ssm put-parameter --name MyParameter --value "secret_value" --type SecureString
```

The following similar example uses the `--key-id` parameter to specify a [customer managed CMK \(p. 3\)](#). The example uses a CMK ID to identify the CMK, but you can use any valid CMK identifier. Because the command omits the `Tier` parameter (`--tier`), Parameter Store creates a standard secure string parameter, not an advanced one.

```
aws ssm put-parameter --name param1 --value "secret" --type SecureString --key-id  
1234abcd-12ab-34cd-56ef-1234567890ab
```

When you get a secure string parameter from Parameter Store, its value is encrypted. To get a parameter, use the [GetParameter](#) operation in the Systems Manager API.

The following example uses the Systems Manager [get-parameter](#) command in the AWS CLI to get the `MyParameter` parameter from Parameter Store without decrypting its value.

```
$ aws ssm get-parameter --name MyParameter  
  
{  
  "Parameter": {  
    "Type": "SecureString",  
    "Name": "MyParameter",  
    "Value":  
    "AQECAHgnOkMROh5LaLXkA4j0+vYi6tmM17Lg/9E464VRo68cvwAAAG8wbQYJKoZIhvcNAQcGoGAWXgIBADBZBgkqhkiG9w0BBwEwH  
  }  
}
```

To decrypt the parameter value before returning it, set the `WithDecryption` parameter of `GetParameter` to `true`. When you use `WithDecryption`, Parameter Store calls the AWS KMS [Decrypt](#) operation on your behalf to decrypt the parameter value. As a result, the `GetParameter` request returns the parameter with a plaintext parameter value, as shown in the following example.

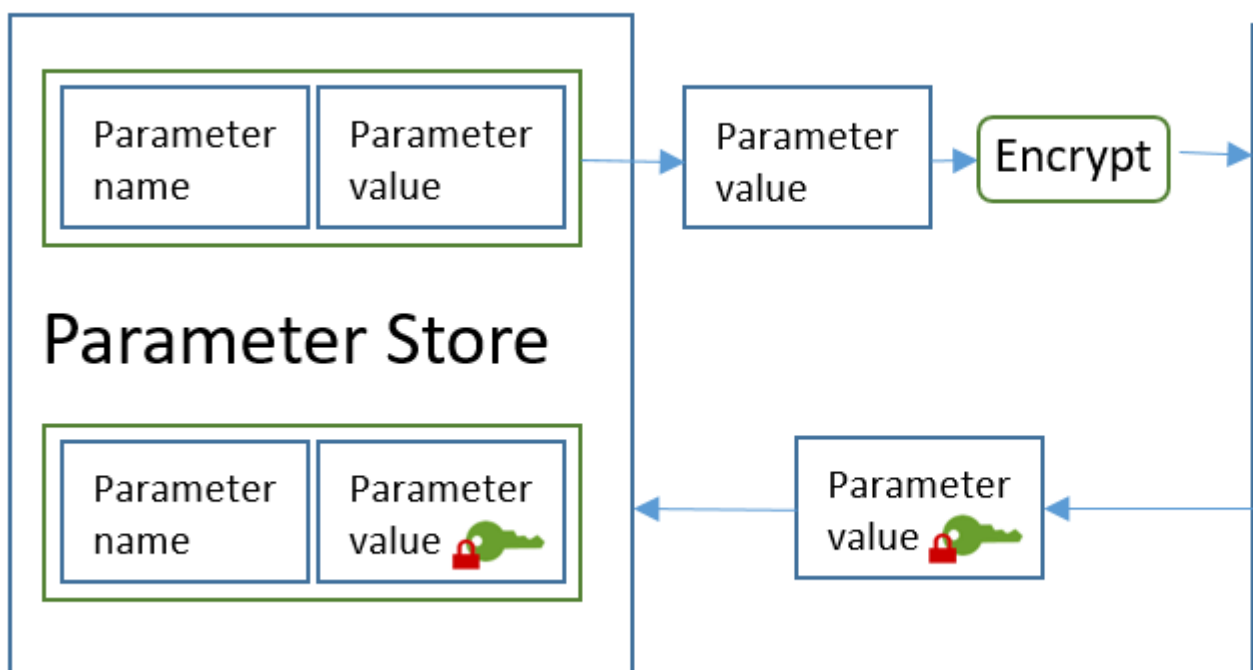

```
$ aws ssm get-parameter --name MyParameter --with-decryption  
  
{  
  "Parameter": {  
    "Type": "SecureString",  
    "Name": "MyParameter",  
    "Value": "secret_value"  }  
}
```

```
}  
}
```

The following workflow shows how Parameter Store uses an AWS KMS CMK to encrypt and decrypt a standard secure string parameter.

## Encrypt a Standard Parameter

1. When you use `PutParameter` to create a secure string parameter, Parameter Store sends an `Encrypt` request to AWS KMS. That request includes the plaintext parameter value, the CMK that you chose, and the [Parameter Store encryption context \(p. 274\)](#). During transmission to AWS KMS, the plaintext value in the secure string parameter is protected by Transport Layer Security (TLS).
2. AWS KMS encrypts the parameter value with the specified CMK and encryption context. It returns the ciphertext to Parameter Store, which stores the parameter name and its encrypted value.

## Decrypt a Standard Parameters

1. When you include the `WithDecryption` parameter in a `GetParameter` request, Parameter Store sends a `Decrypt` request to AWS KMS with the encrypted secure string parameter value and the [Parameter Store encryption context \(p. 274\)](#).
2. AWS KMS uses the same CMK and the supplied encryption context to decrypt the encrypted value. It returns the plaintext (decrypted) parameter value to Parameter Store. During transmission, the plaintext data is protected by TLS.
3. Parameter Store returns the plaintext parameter value to you in the `GetParameter` response.

## Protecting Advanced Secure String Parameters

When you use `PutParameter` to create an advanced secure string parameter, Parameter Store uses [envelope encryption](#) with the AWS Encryption SDK and a symmetric AWS KMS customer master key

(CMK) to protect the parameter value. Each advanced parameter value is encrypted under a unique data key, and the data key is encrypted under an AWS KMS CMK. You can use the [AWS managed CMK \(p. 4\)](#) for the account (`aws/ssm`) or any customer managed CMK.

The [AWS Encryption SDK](#) is an open-source, client-side library that helps you to encrypt and decrypt data using industry standards and best practices. It's supported on multiple platforms and in multiple programming languages, including a command-line interface. You can view the source code and contribute to its development in GitHub.

For each secure string parameter value, Parameter Store calls the AWS Encryption SDK to encrypt the parameter value using a unique data key that AWS KMS generates ([GenerateDataKey](#)). The AWS Encryption SDK returns to Parameter Store an [encrypted message](#) that includes the encrypted parameter value and an encrypted copy of the unique data key. Parameter Store stores the entire encrypted message in the secure string parameter value. Then, when you get an advanced secure string parameter value, Parameter Store uses the AWS Encryption SDK to decrypt the parameter value. This requires a call to AWS KMS to decrypt the encrypted data key.

To create an advanced secure string parameter, use the [PutParameter](#) operation in the Systems Manager API. Set the value of `Tier` parameter to `Advanced`. Include a `Type` parameter with a value of `SecureString`. To specify an AWS KMS CMK, use the `KeyId` parameter. The default is the AWS managed CMK for your account, `aws/ssm`.

```
aws ssm put-parameter --name MyParameter --value "secret_value" --type SecureString --tier Advanced
```

The following similar example uses the `--key-id` parameter to specify a [customer managed CMK \(p. 3\)](#). The example uses the Amazon Resource Name (ARN) of the CMK, but you can use any valid CMK identifier.

```
aws ssm put-parameter --name MyParameter --value "secret_value"
--type SecureString --tier Advanced --key-id arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab
```

When you get a secure string parameter from Parameter Store, its value is the encrypted message that the AWS Encryption SDK returned. To get a parameter, use the [GetParameter](#) operation in the Systems Manager API.

The following example uses the Systems Manager `GetParameter` operation to get the `MyParameter` parameter from Parameter Store without decrypting its value.

```
$ aws ssm get-parameter --name MyParameter

{
  "Parameter": {
    "Type": "SecureString",
    "Name": "MyParameter",
    "Value":
    "AQECAHgnOkMROh5LaLXkA4j0+vYi6tmM17Lg/9E464VRo68cvwAAAG8wbQYJKoZIhvcNAQcGoGAWXgIBADBZBgkqhkiG9w0BBwEwH
  }
}
```

To decrypt the parameter value before returning it, set the `WithDecryption` parameter of `GetParameter` to `true`. When you use `WithDecryption`, Parameter Store calls the AWS KMS [Decrypt](#) operation on your behalf to decrypt the parameter value. As a result, the `GetParameter` request returns the parameter with a plaintext parameter value, as shown in the following example.

```
$ aws ssm get-parameter --name MyParameter --with-decryption
```

```
{
  "Parameter": {
    "Type": "SecureString",
    "Name": "MyParameter",
    "Value": "secret_value"
  }
}
```

You cannot convert an advanced secure string parameter to a standard one, but you can convert a standard secure string to an advanced one. To convert a standard secure string parameter to an advanced secure string, use the `PutParameter` operation with the `Overwrite` parameter. The `Type` must be `SecureString` and the `Tier` value must be `Advanced`. The `KeyId` parameter, which identifies a customer managed CMK, is optional. If you omit it, Parameter Store uses the AWS managed CMK for the account. You can specify any CMK that the principal has permission to use, even if you used a different CMK to encrypt the standard parameter.

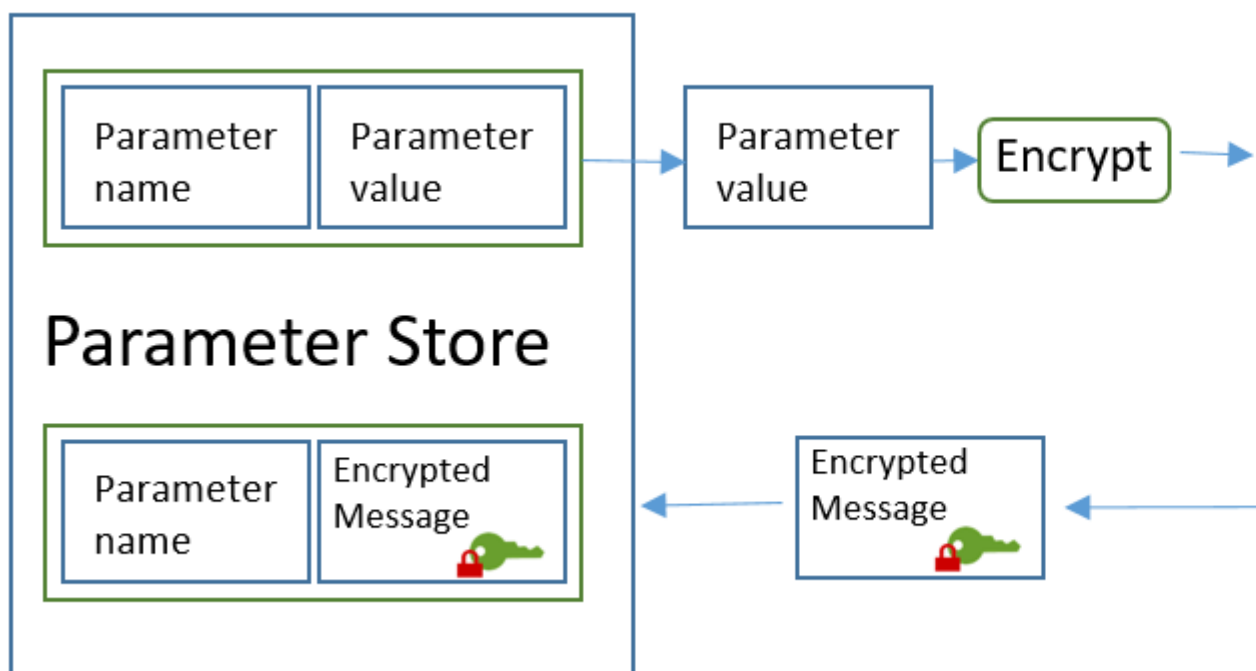

When you use the `Overwrite` parameter, Parameter Store uses the AWS Encryption SDK to encrypt the parameter value. Then it stores the newly encrypted message in Parameter Store.

```
$ aws ssm put-parameter --name myStdParameter --value "secret_value" --type SecureString
--tier Advanced --key-id 1234abcd-12ab-34cd-56ef-1234567890ab --overwrite
```

The following workflow shows how Parameter Store uses an AWS KMS CMK to encrypt and decrypt an advanced secure string parameter.

## Encrypt an Advanced Parameter

1. When you use `PutParameter` to create an advanced secure string parameter, Parameter Store uses the AWS Encryption SDK and AWS KMS to encrypt the parameter value. Parameter Store calls the AWS Encryption SDK with the parameter value, the AWS KMS CMK that you specified, and the [Parameter Store encryption context](#) (p. 274).
2. The AWS Encryption SDK sends a [GenerateDataKey](#) request to AWS KMS with the identifier of the CMK that you specified and the Parameter Store encryption context. AWS KMS returns two copies of the unique data key: one in plaintext and one encrypted under the CMK. (The encryption context is used when encrypting the data key.)
3. The AWS Encryption SDK uses the plaintext data key to encrypt the parameter value. It returns an [encrypted message](#) that includes the encrypted parameter value, the encrypted data key, and other data, including the Parameter Store encryption context.
4. Parameter Store stores the encrypted message as the parameter value.

## Decrypt an Advanced Parameter

1. You can include the `WithDecryption` parameter in a `GetParameter` request to get an advanced secure string parameter. When you do, Parameter Store passes the [encrypted message](#) from the parameter value to a decryption method of the AWS Encryption SDK.
2. The AWS Encryption SDK calls the KMS [Decrypt](#) operation. It passes in the encrypted data key and the Parameter Store encryption context from the encrypted message.
3. AWS KMS uses the CMK and the Parameter Store encryption context to decrypt the encrypted data key. Then it returns the plaintext (decrypted) data key to the AWS Encryption SDK.
4. The AWS Encryption SDK uses the plaintext data key to decrypt the parameter value. It returns the plaintext parameter value to Parameter Store.
5. Parameter Store verifies the encryption context and returns the plaintext parameter value to you in the `GetParameter` response.

## Setting Permissions to Encrypt and Decrypt Parameter Values

To encrypt a standard secure string parameter value, the user needs `kms:Encrypt` permission. To encrypt an advanced secure string parameter value, the user needs `kms:GenerateDataKey` permission. To decrypt either type of secure string parameter value, the user needs `kms:Decrypt` permission.

You can use IAM policies to allow or deny permission for a user to call the Systems Manager `PutParameter` and `GetParameter` operations.

If you are using customer managed CMKs to encrypt your secure string parameter values, you can use IAM policies and key policies to manage encrypt and decrypt permissions. However, you cannot establish access control policies for the default `aws/ssm` CMK. For detailed information about controlling access to customer managed CMKs, see [Authentication and Access Control for AWS KMS](#) (p. 46).

The following example shows an IAM policy designed for standard secure string parameters. It allows the user to call the Systems Manager `PutParameter` operation on all parameters in the `FinancialParameters` path. The policy also allows the user to call the AWS KMS `Encrypt` operation on an example customer managed CMK.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": "arn:aws:ssm:us-west-2:11112223333:parameter/FinancialParameters/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Encrypt"
      ],
      "Resource": "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
  ]
}
```

The next example shows an IAM policy that is designed for advanced secure string parameters. It allows the user to call the Systems Manager `PutParameter` operation on all parameters in the `ReservedParameters` path. The policy also allows the user to call the AWS KMS `GenerateDataKey` operation on an example customer managed CMK.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:PutParameter"
      ],
      "Resource": "arn:aws:ssm:us-west-2:11112223333:parameter/ReservedParameters/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:GenerateDataKey"
      ],
      "Resource": "arn:aws:kms:us-west-2:11112223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    }
  ]
}
```

The final example also shows an IAM policy that can be used for standard or advanced secure string parameters. It allows the user to call the Systems Manager `GetParameter` operations (and related operations) on all parameters in the `ITParameters` path. The policy also allows the user to call the AWS KMS `Decrypt` operation on an example customer managed CMK.

```
{
  "Version": "2012-10-17",
  "Statement": [
```

```
{
  "Effect": "Allow",
  "Action": [
    "ssm:GetParameter*"
  ],
  "Resource": "arn:aws:ssm:us-west-2:111122223333:parameter/ITParameters/*"
},
{
  "Effect": "Allow",
  "Action": [
    "kms:Decrypt"
  ],
  "Resource": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
}
]
```

## Parameter Store Encryption Context

An *encryption context* is a set of key-value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

You can also use the encryption context to identify a cryptographic operation in audit records and logs. The encryption context appears in plaintext in logs, such as [AWS CloudTrail](#) logs.

The AWS Encryption SDK also takes an encryption context, although it handles it differently. Parameter Store supplies the encryption context to the encryption method. The AWS Encryption SDK cryptographically binds the encryption context to the encrypted data. It also includes the encryption context in plain text in the header of the encrypted message that it returns. However, unlike AWS KMS, the AWS Encryption SDK decryption methods do not take an encryption context as input. Instead, when it decrypts data, the AWS Encryption SDK gets the encryption context from the encrypted message. Parameter Store verifies that the encryption context includes the value that it expects before returning the plaintext parameter value to you.

Parameter Store uses the following encryption context in its cryptographic operations:

- Key: `PARAMETER_ARN`
- Value: The Amazon Resource Name (ARN) of the parameter that is being encrypted.

The format of the encryption context is as follows:

```
"PARAMETER_ARN": "arn:aws:ssm:<REGION_NAME>:<ACCOUNT_ID>:parameter/<parameter-name>"
```

For example, Parameter Store includes this encryption context in calls to encrypt and decrypt the `MyParameter` parameter in an example AWS account and region.

```
"PARAMETER_ARN": "arn:aws:ssm:us-west-2:111122223333:parameter/MyParameter"
```

If the parameter is in a Parameter Store hierarchical path, the path and name are included in the encryption context. For example, this encryption context is used when encrypting and decrypting the `MyParameter` parameter in the `/ReadableParameters` path in an example AWS account and region.

```
"PARAMETER_ARN": "arn:aws:ssm:us-west-2:111122223333:parameter/ReadableParameters/MyParameter"
```

You can decrypt an encrypted secure string parameter value by calling the AWS KMS `Decrypt` operation with the correct encryption context and the encrypted parameter value that the Systems Manager `GetParameter` operation returns. However, we encourage you to decrypt Parameter Store parameter values by using the `GetParameter` operation with the `WithDecryption` parameter.

You can also include the encryption context in an IAM policy. For example, you can permit a user to decrypt only one particular parameter value or set of parameter values.

The following example IAM policy statement allows the user to the get value of the `MyParameter` parameter and to decrypt its value using the specified CMK. However the permissions apply only when the encryption context matches specified string. These permissions do not apply to any other parameter or CMK, and the call to `GetParameter` fails if the encryption context does not match the string.

Before using a policy statement like this one, replace the example ARNs with valid values.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ssm:GetParameter*"
      ],
      "Resource": "arn:aws:ssm:us-west-2:111122223333:parameter/MyParameter",
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:Decrypt"
      ],
      "Resource": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab",
      "Condition": {
        "StringEquals": {
          "kms:EncryptionContext:PARAMETER_ARN": "arn:aws:ssm:us-west-2:111122223333:parameter/MyParameter"
        }
      }
    }
  ]
}
```

## Troubleshooting CMK Issues in Parameter Store

To perform any operation on a secure string parameter, Parameter Store must be able to use the AWS KMS CMK that you specify for your intended operation. Most of the Parameter Store failures related to CMKs are caused by the following problems:

- The credentials that an application is using do not have permission to perform the specified action on the CMK.

To fix this error, run the application with different credentials or revise the IAM or key policy that is preventing the operation. For help with AWS KMS IAM and key policies, see [Authentication and Access Control for AWS KMS](#) (p. 46).

- The CMK is not found.

This typically happens when you use an incorrect identifier for the CMK. [Find the correct identifiers](#) (p. 32) for the CMK and try the command again.

- The CMK is not enabled. When this occurs, Parameter Store returns an `InvalidKeyId` exception with a detailed error message from AWS KMS. If the CMK state is `Disabled`, [enable it](#) (p. 41). If it is `Pending`

Import, complete the [import procedure \(p. 147\)](#). If the key state is Pending Deletion, [cancel the key deletion \(p. 162\)](#) or use a different CMK.

To find the [key state \(p. 223\)](#) of a CMK in the AWS KMS console, on the **Customer managed keys** or **AWS managed keys** page, see the [Status column \(p. 23\)](#). To use the AWS KMS API to find the status of a CMK, use the [DescribeKey](#) operation.

## How Amazon WorkMail Uses AWS KMS

This topic discusses how Amazon WorkMail uses AWS KMS to encrypt email messages.

### Topics

- [Amazon WorkMail Overview \(p. 276\)](#)
- [Amazon WorkMail Encryption \(p. 276\)](#)
- [Authorizing Use of the CMK \(p. 279\)](#)
- [Amazon WorkMail Encryption Context \(p. 280\)](#)
- [Monitoring Amazon WorkMail Interaction with AWS KMS \(p. 281\)](#)

## Amazon WorkMail Overview

[Amazon WorkMail](#) is a secure, managed business email and calendaring service with support for existing desktop and mobile email clients. You can create an Amazon WorkMail organization and assign to it one or more email domains that you own. Then you can create mailboxes for the email users and distribution groups in the organization.

Amazon WorkMail transparently encrypts all messages in the mailboxes of all Amazon WorkMail organizations before the messages are written to disk and transparently decrypts the messages when users access them. There is no option to disable encryption. To protect the encryption keys that protect the messages, Amazon WorkMail is integrated with AWS Key Management Service (AWS KMS).

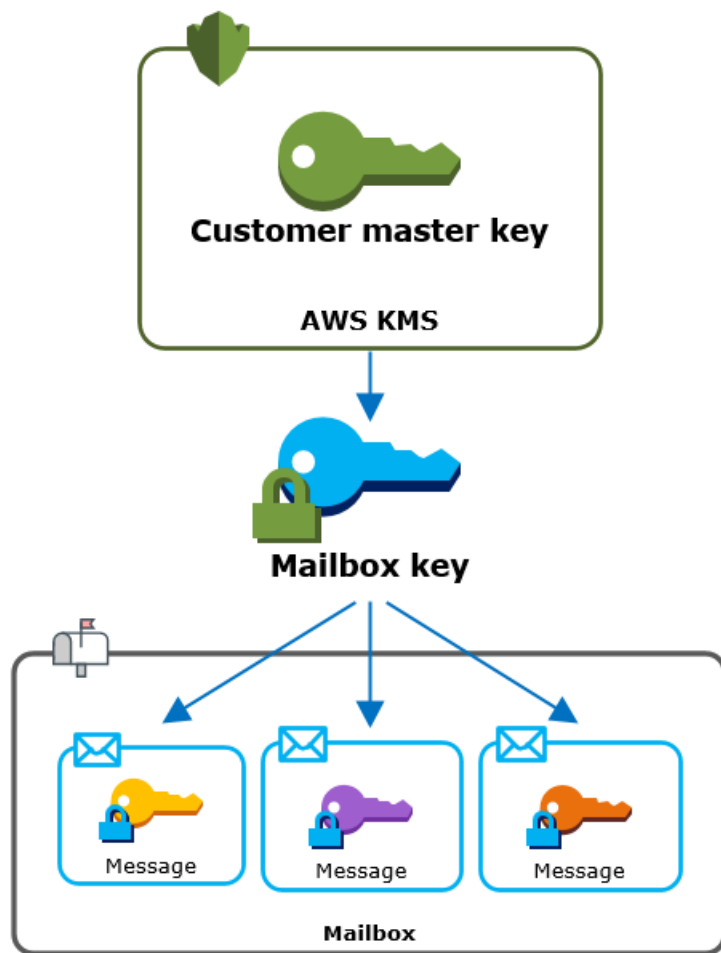

Amazon WorkMail also provides an option for enabling users to [send signed or encrypted email](#). This encryption feature does not use AWS KMS.

## Amazon WorkMail Encryption

In Amazon WorkMail, each organization can contain multiple mailboxes, one for each user in the organization. All messages, including email and calendar items, are stored in the user's mailbox.

To protect the contents of the mailboxes in your Amazon WorkMail organizations, Amazon WorkMail encrypts all mailbox messages before they are written to disk. No customer-provided information is stored in plaintext.

Each message is encrypted under a unique data encryption key. The message key is protected by a mailbox key, which is a unique encryption key that is used only for that mailbox. The mailbox key is encrypted under an AWS KMS customer master key (CMK) for the organization that never leaves AWS KMS unencrypted. The following diagram shows the relationship of the encrypted messages, encrypted message keys, encrypted mailbox key, and the CMK for the organization in AWS KMS.

## A CMK for the Organization

When you create an Amazon WorkMail organization, you can select an AWS KMS customer master key (CMK) for the organization. This CMK protects all mailbox keys in that organization.

If you use the [Quick Setup](#) procedure to create your organization, Amazon WorkMail uses the [AWS managed CMK \(p. 2\)](#) for Amazon WorkMail (`aws/workmail`) in your AWS account. If you use the [Standard Setup](#), you can select the AWS managed CMK for Amazon WorkMail or a [customer managed CMK \(p. 2\)](#) that you own and manage. You can select the same CMK or a different CMK for each of your organizations, but you cannot change the CMK once you have selected it.

### Important

Amazon WorkMail supports only symmetric CMKs. You cannot use an asymmetric CMK to encrypt data in Amazon WorkMail. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

To find the CMK for your organization, use the AWS CloudTrail log entry that records calls to AWS KMS.

## A Unique Encryption Key for Each Mailbox

When you create a new mailbox, Amazon WorkMail generates a unique 256-bit [Advanced Encryption Standard](#) (AES) symmetric encryption key for the mailbox, known as its *mailbox key*, outside of AWS KMS. Amazon WorkMail uses the mailbox key to protect the encryption keys for each message in the mailbox.

To protect the mailbox key, Amazon WorkMail calls AWS KMS to encrypt the mailbox key under the CMK for the organization. Then it stores the encrypted mailbox key in the mailbox metadata.

**Note**

Amazon WorkMail uses a symmetric mailbox encryption key to protect message keys. Previously, Amazon WorkMail protected each mailbox with an asymmetric key pair. It used the public key to encrypt each message key and the private key to decrypt it. The private mailbox key was protected by the CMK for the organization. Existing mailboxes might still use an asymmetric mailbox key pair. This change does not affect the security of the mailbox or its messages.

## A Unique Encryption Key for Each Message

When a message is added to the mailbox, Amazon WorkMail generates a unique 256-bit AES symmetric encryption key for the message outside of AWS KMS. It uses this *message key* to encrypt the message. Amazon WorkMail encrypts the message key under the mailbox key and stores the encrypted message key with the message. Then, it encrypts the mailbox key under the CMK for the organization.

## Creating a New Mailbox

When Amazon WorkMail creates a new mailbox, it uses the following process to prepare the mailbox to hold encrypted messages.

- Amazon WorkMail generates a unique 256-bit AES symmetric encryption key for the mailbox outside of AWS KMS.
- Amazon WorkMail calls the AWS KMS [Encrypt](#) operation. It passes in the mailbox key and the identifier of the customer master key (CMK) for the organization. AWS KMS returns a ciphertext of the mailbox key encrypted under the CMK.
- Amazon WorkMail stores the encrypted mailbox key with the mailbox metadata.

## Encrypting a Mailbox Message

To encrypt a message, Amazon WorkMail uses the following process.

1. Amazon WorkMail generates a unique 256-bit AES symmetric key for the message. It uses the plaintext message key and the Advanced Encryption Standard (AES) algorithm to encrypt the message outside of AWS KMS.
2. To protect the message key under the mailbox key, Amazon WorkMail needs to decrypt the mailbox key, which is always stored in its encrypted form.

Amazon WorkMail calls the AWS KMS [Decrypt](#) operation and passes in the encrypted mailbox key. AWS KMS uses the CMK for the organization to decrypt the mailbox key and it returns the plaintext mailbox key to Amazon WorkMail.

3. Amazon WorkMail uses the plaintext mailbox key and the Advanced Encryption Standard (AES) algorithm to encrypt the message key outside of AWS KMS.
4. Amazon WorkMail stores the encrypted message key in the metadata of the encrypted message so it is available to decrypt it.

## Decrypting a Mailbox Message

To decrypt a message, Amazon WorkMail uses the following process.

1. Amazon WorkMail calls the AWS KMS [Decrypt](#) operation and passes in the encrypted mailbox key. AWS KMS uses the CMK for the organization to decrypt the mailbox key and it returns the plaintext mailbox key to Amazon WorkMail.

2. Amazon WorkMail uses the plaintext mailbox key and the Advanced Encryption Standard (AES) algorithm to decrypt the encrypted message key outside of AWS KMS.
3. Amazon WorkMail uses the plaintext message key to decrypt the encrypted message.

## Caching Mailbox Keys

To improve performance and minimize calls to AWS KMS, Amazon WorkMail caches each plaintext mailbox key for each client locally for up to one minute. At the end of the caching period, the mailbox key is removed. If the mailbox key for that client is required during the caching period, Amazon WorkMail can get it from the cache instead of calling AWS KMS. The mailbox key is protected in the cache and is never written to disk in plaintext.

## Authorizing Use of the CMK

When Amazon WorkMail uses a customer master key (CMK) in cryptographic operations, it acts on behalf of the mailbox administrator.

To use the AWS KMS customer master key (CMK) for a secret on your behalf, the administrator must have the following permissions. You can specify these required permissions in an IAM policy or key policy.

- `kms:Encrypt`
- `kms:Decrypt`
- `kms:CreateGrant`

To allow the CMK to be used only for requests that originate in Amazon WorkMail, you can use the [kms:ViaService \(p. 111\)](#) condition key with the `workmail.<region>.amazonaws.com` value.

You can also use the keys or values in the [encryption context \(p. 280\)](#) as a condition for using the CMK for cryptographic operations. For example, you can use a string condition operator in an IAM or key policy document or use a grant constraint in a grant.

### Key Policy for the Organization CMK

The key policy for the AWS managed CMK for Amazon WorkMail gives users permission to use the CMK for specified operations only when Amazon WorkMail makes the request on the user's behalf. The key policy does not allow any user to use the CMK directly.

This key policy, like the policies of all [AWS managed keys](#), is established by the service. You cannot change the key policy, but you can view it at any time. For details, see [Viewing a Key Policy \(p. 61\)](#).

The policy statements in the key policy have the following effect:

- Allow users in the account and Region to use the CMK for cryptographic operations and to create grants, but only when the request comes from Amazon WorkMail on their behalf. The `kms:ViaService` condition key enforces this restriction.
- Allows the AWS account to create IAM policies that allow users to view CMK properties and revoke grants.

The following is a key policy for an example AWS managed CMK for Amazon WorkMail.

```
{
  "Version" : "2012-10-17",
  "Id" : "auto-workmail-1",
```

```
"Statement" : [ {
  "Sid" : "Allow access through WorkMail for all principals in the account that are
authorized to use WorkMail",
  "Effect" : "Allow",
  "Principal" : {
    "AWS" : "*"
  },
  "Action" : [ "kms:Decrypt", "kms:CreateGrant", "kms:ReEncrypt*", "kms:DescribeKey",
"kms:Encrypt" ],
  "Resource" : "*",
  "Condition" : {
    "StringEquals" : {
      "kms:ViaService" : "workmail.us-east-1.amazonaws.com",
      "kms:CallerAccount" : "111122223333"
    }
  }
}, {
  "Sid" : "Allow direct access to key metadata to the account",
  "Effect" : "Allow",
  "Principal" : {
    "AWS" : "arn:aws:iam::111122223333:root"
  },
  "Action" : [ "kms:Describe*", "kms:List*", "kms:Get*", "kms:RevokeGrant" ],
  "Resource" : "*"
} ]
}
```

### Using Grants to Authorize Amazon WorkMail

In addition to key policies, Amazon WorkMail uses grants to add permissions to the CMK for each organization. To view the grants on the CMK in your account, use the [ListGrants](#) operation.

Amazon WorkMail uses grants to add the following permissions to the CMK for the organization.

- Add the `kms:Encrypt` permission to allow Amazon WorkMail to encrypt the mailbox key.
- Add the `kms:Decrypt` permission to allow Amazon WorkMail to use the CMK to decrypt the mailbox key. Amazon WorkMail requires this permission in a grant because the request to read mailbox messages uses the security context of the user who is reading the message. The request does not use the credentials of the AWS account. Amazon WorkMail creates this grant when you select a CMK for the organization.

To create the grants, Amazon WorkMail calls [CreateGrant](#) on behalf of the user who created the organization. Permission to create the grant comes from the key policy. This policy allows account users to call `CreateGrant` on the CMK for the organization when Amazon WorkMail makes the request on an authorized user's behalf.

The key policy also allows the account root to revoke the grant on the AWS managed key. However, if you revoke the grant, Amazon WorkMail cannot decrypt the encrypted data in your mailboxes.

## Amazon WorkMail Encryption Context

An [encryption context](#) (p. 12) is a set of key-value pairs that contain arbitrary nonsecret data. When you include an encryption context in a request to encrypt data, AWS KMS cryptographically binds the encryption context to the encrypted data. To decrypt the data, you must pass in the same encryption context.

Amazon WorkMail uses the same encryption context format in all AWS KMS cryptographic operations. You can use the encryption context to identify a cryptographic operation in audit records and logs, such as [AWS CloudTrail](#), and as a condition for authorization in policies and grants.

In its [Encrypt](#) and [Decrypt](#) requests to AWS KMS, Amazon WorkMail uses an encryption context where the key is `aws:workmail:arn` and the value is the Amazon Resource Name (ARN) of the organization.

```
"aws:workmail:arn": "arn:aws:workmail:region:account ID:organization/organization ID"
```

For example, the following encryption context includes an example organization ARN in the US East (Ohio) (us-east-2) Region.

```
"aws:workmail:arn": "arn:aws:workmail:us-east-2:111122223333:organization/  
m-68755160c4cb4e29a2b2f8fb58f359d7"
```

## Monitoring Amazon WorkMail Interaction with AWS KMS

You can use AWS CloudTrail and Amazon CloudWatch Logs to track the requests that Amazon WorkMail sends to AWS KMS on your behalf.

### Encrypt

When you create a new mailbox, Amazon WorkMail generates a mailbox key and calls AWS KMS to encrypt the mailbox key. Amazon WorkMail sends an [Encrypt](#) request to AWS KMS with the plaintext mailbox key and an identifier for the CMK of the Amazon WorkMail organization.

The event that records the `Encrypt` operation is similar to the following example event. The user is the Amazon WorkMail service. The parameters include the CMK ID (`keyId`) and the encryption context for the Amazon WorkMail organization. Amazon WorkMail also passes in the mailbox key, but that is not recorded in the CloudTrail log.

```
{  
  "eventVersion": "1.05",  
  "userIdentity": {  
    "type": "AWSService",  
    "invokedBy": "workmail.eu-west-1.amazonaws.com"  
  },  
  "eventTime": "2019-02-19T10:01:09Z",  
  "eventSource": "kms.amazonaws.com",  
  "eventName": "Encrypt",  
  "awsRegion": "eu-west-1",  
  "sourceIPAddress": "workmail.eu-west-1.amazonaws.com",  
  "userAgent": "workmail.eu-west-1.amazonaws.com",  
  "requestParameters": {  
    "encryptionContext": {  
      "aws:workmail:arn": "arn:aws:workmail:eu-west-1:111122223333:organization/m-  
c6981ff7642446fa8772ba99c690e455"  
    },  
    "keyId": "arn:aws:kms:eu-  
west-1:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d"  
  },  
  "responseElements": null,  
  "requestID": "76e96b96-7e24-4faf-a2d6-08ded2eaf63c",  
  "eventID": "d5a59c18-128a-4082-aa5b-729f7734626a",  
  "readOnly": true,  
  "resources": [  
    {  
      "ARN": "arn:aws:kms:eu-  
west-1:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d",  
      "accountId": "111122223333",  
      "type": "AWS::KMS::Key"  
    }  
  ]  
}
```

```
    }
  ],
  "eventType": "AwsApiCall",
  "recipientAccountId": "111122223333",
  "sharedEventID": "d08e60f1-097e-4a00-b7e9-10bc3872d50c"
}
```

## Decrypt

When you add, view, or delete a mailbox message, Amazon WorkMail asks AWS KMS to decrypt the mailbox key. Amazon WorkMail sends an [Decrypt](#) request to AWS KMS with the encrypted mailbox key and an identifier for the CMK of the Amazon WorkMail organization.

The event that records the Decrypt operation is similar to the following example event. The user is the Amazon WorkMail service. The parameters include the encrypted mailbox key (as a ciphertext blob), which is not recorded in the log, and the encryption context for the Amazon WorkMail organization. AWS KMS derives the ID of the CMK from the ciphertext.

```
{
  "eventVersion": "1.05",
  "userIdentity": {
    "type": "AWSService",
    "invokedBy": "workmail.eu-west-1.amazonaws.com"
  },
  "eventTime": "2019-02-20T11:51:10Z",
  "eventSource": "kms.amazonaws.com",
  "eventName": "Decrypt",
  "awsRegion": "eu-west-1",
  "sourceIPAddress": "workmail.eu-west-1.amazonaws.com",
  "userAgent": "workmail.eu-west-1.amazonaws.com",
  "requestParameters": {
    "encryptionContext": {
      "aws:workmail:arn": "arn:aws:workmail:eu-west-1:111122223333:organization/m-c6981ff7642446fa8772ba99c690e455"
    }
  },
  "responseElements": null,
  "requestID": "4a32dda1-34d9-4100-9718-674b8e0782c9",
  "eventID": "ea9fd966-98e9-4b7b-b377-6e5a397a71de",
  "readOnly": true,
  "resources": [
    {
      "ARN": "arn:aws:kms:eu-west-1:111122223333:key/1a2b3c4d-5e6f-1a2b-3c4d-5e6f1a2b3c4d",
      "accountId": "111122223333",
      "type": "AWS::KMS::Key"
    }
  ],
  "eventType": "AwsApiCall",
  "recipientAccountId": "111122223333",
  "sharedEventID": "241e1e5b-ff64-427a-a5b3-7949164d0214"
}
```

## How Amazon WorkSpaces Uses AWS KMS

You can use [Amazon WorkSpaces](#) to provision a cloud-based desktop (a *WorkSpace*) for each of your end users. When you launch a new WorkSpace, you can choose to encrypt its volumes and decide which AWS KMS [customer master key \(p. 2\)](#) (CMK) to use for the encryption. You can choose the [AWS managed CMK \(p. 4\)](#) for Amazon WorkSpaces ([aws/workspaces](#)) or a symmetric [customer managed CMK \(p. 3\)](#).

### Important

Amazon WorkSpaces supports only symmetric CMKs. You cannot use an asymmetric CMK to encrypt the volumes in an Amazon WorkSpaces. To determine whether a CMK is symmetric or asymmetric, see [Identifying Symmetric and Asymmetric CMKs \(p. 33\)](#).

For more information about creating WorkSpaces with encrypted volumes, go to [Encrypt a Workspace](#) in the *Amazon WorkSpaces Administration Guide*.

### Topics

- [Overview of Amazon WorkSpaces Encryption Using AWS KMS \(p. 283\)](#)
- [Amazon WorkSpaces Encryption Context \(p. 284\)](#)
- [Giving Amazon WorkSpaces Permission to Use A CMK On Your Behalf \(p. 284\)](#)

## Overview of Amazon WorkSpaces Encryption Using AWS KMS

When you create WorkSpaces with encrypted volumes, Amazon WorkSpaces uses Amazon Elastic Block Store (Amazon EBS) to create and manage those volumes. Both services use your KMS customer master key (CMK) to work with the encrypted volumes. For more information about EBS volume encryption, see the following documentation:

- [How Amazon Elastic Block Store \(Amazon EBS\) Uses AWS KMS \(p. 243\)](#) in this guide
- [Amazon EBS Encryption](#) in the *Amazon EC2 User Guide for Windows Instances*

When you launch WorkSpaces with encrypted volumes, the end-to-end process works like this:

1. You specify the CMK to use for encryption as well as the Workspace's user and directory. This action creates a [grant \(p. 115\)](#) that allows Amazon WorkSpaces to use your CMK only for this Workspace—that is, only for the Workspace associated with the specified user and directory.
2. Amazon WorkSpaces creates an encrypted EBS volume for the Workspace and specifies the CMK to use as well as the volume's user and directory (the same information that you specified at [Step 1 \(p. 283\)](#)). This action creates a [grant \(p. 115\)](#) that allows Amazon EBS to use your CMK only for this Workspace and volume—that is, only for the Workspace associated with the specified user and directory, and only for the specified volume.
3. Amazon EBS requests a volume data key that is encrypted under your CMK and specifies the Workspace user's `Sid` and directory ID as well as the volume ID as encryption context.
4. AWS KMS creates a new data key, encrypts it under your CMK, and then sends the encrypted data key to Amazon EBS.
5. Amazon WorkSpaces uses Amazon EBS to attach the encrypted volume to your Workspace. Amazon EBS sends the encrypted data key to AWS KMS with a [Decrypt](#) request and specifies the Workspace user's `Sid`, its directory ID, and the the volume ID, which is used as the [encryption context \(p. 284\)](#).
6. AWS KMS uses your CMK to decrypt the data key, and then sends the plaintext data key to Amazon EBS.
7. Amazon EBS uses the plaintext data key to encrypt all data going to and from the encrypted volume. Amazon EBS keeps the plaintext data key in memory for as long as the volume is attached to the Workspace.
8. Amazon EBS stores the encrypted data key (received at [Step 4 \(p. 283\)](#)) with the volume metadata for future use in case you reboot or rebuild the Workspace.
9. When you use the AWS Management Console to remove a Workspace (or use the [TerminateWorkspaces](#) action in the Amazon WorkSpaces API), Amazon WorkSpaces and Amazon EBS retire the grants that allowed them to use your CMK for that Workspace.

## Amazon WorkSpaces Encryption Context

Amazon WorkSpaces doesn't use your customer master key (CMK) directly for cryptographic operations (such as [Encrypt](#), [Decrypt](#), [GenerateDataKey](#), etc.), which means Amazon WorkSpaces doesn't send requests to AWS KMS that include an [encryption context](#) (p. 12). However, when Amazon EBS requests an encrypted data key for the encrypted volumes of your WorkSpaces ([Step 3](#) (p. 283) in the [Overview of Amazon WorkSpaces Encryption Using AWS KMS](#) (p. 283)) and when it requests a plaintext copy of that data key ([Step 5](#) (p. 283)), it includes encryption context in the request. The encryption context provides [additional authenticated data](#) (AAD) that AWS KMS uses to ensure data integrity. The encryption context is also written to your AWS CloudTrail log files, which can help you understand why a given customer master key (CMK) was used. Amazon EBS uses the following for the encryption context:

- The `sid` of the AWS Directory Service user that is associated with the WorkSpace
- The directory ID of the AWS Directory Service directory that is associated with the WorkSpace
- The volume ID of the encrypted volume

The following example shows a JSON representation of the encryption context that Amazon EBS uses:

```
{
  "aws:workspaces:sid-directoryid":
    "[S-1-5-21-277731876-1789304096-451871588-1107]@[d-1234abcd01]",
  "aws:ebs:id": "vol-1234abcd"
}
```

## Giving Amazon WorkSpaces Permission to Use A CMK On Your Behalf

You can protect your workspace data under the AWS managed CMK for Amazon WorkSpaces (**aws/workspaces**) or a customer managed CMK. If you use a customer managed CMK, you need to give Amazon WorkSpaces permission to use the CMK on behalf of the Amazon WorkSpaces administrators in your account. The AWS managed CMK for Amazon WorkSpaces has the required permissions by default.

To prepare your customer managed CMK for use with Amazon WorkSpaces, use the following procedure.

1. [Add the WorkSpaces administrators to the list of key users in the CMK's key policy](#) (p. 284)
2. [Give the WorkSpaces administrators additional permissions with an IAM policy](#) (p. 285)

Amazon WorkSpaces administrators also need permission to use Amazon WorkSpaces. For more information about these permissions, go to [Controlling Access to Amazon WorkSpaces Resources](#) in the *Amazon WorkSpaces Administration Guide*.

## Part 1: Adding WorkSpaces Administrators to a CMK's Key Users

To give Amazon WorkSpaces administrators the permissions that they require, you can use the AWS Management Console or the AWS KMS API.

### To add WorkSpaces administrators as key users for a CMK (Console)

1. Sign in to the AWS Management Console and open the AWS Key Management Service (AWS KMS) console at <https://console.aws.amazon.com/kms>.
2. To change the AWS Region, use the Region selector in the upper-right corner of the page.
3. In the navigation pane, choose **Customer managed keys**.

4. Choose the key ID or alias of your preferred customer managed CMK.
5. In the **Key policy** section, under **Key users**, choose **Add**.
6. In the list of IAM users and roles, select the users and roles that correspond to your WorkSpaces administrators, and then choose **Attach**.

## To add WorkSpaces administrators as key users for a CMK (KMS API)

1. Use the [GetKeyPolicy](#) operation to get the existing key policy, and then save the policy document to a file.
2. Open the policy document in your preferred text editor. Add the IAM users and roles that correspond to your WorkSpaces administrators to the policy statements that [give permission to key users](#) (p. 54). Then save the file.
3. Use the [PutKeyPolicy](#) operation to apply the key policy to the CMK.

## Part 2: Giving WorkSpaces Administrators Extra Permissions

If you are using a customer managed CMK to protect your Amazon WorkSpaces data, in addition to the permissions in the key users section of the [default key policy](#) (p. 51), WorkSpaces administrators need permission to create [grants](#) (p. 115) on the CMK. Also, if they use the [AWS Management Console](#) to create WorkSpaces with encrypted volumes, WorkSpaces administrators need permission to list aliases and list keys. For information about creating and editing IAM user policies, see [Managed Policies and Inline Policies](#) in the *IAM User Guide*.

To give these permissions to your WorkSpaces administrators, use an IAM policy. Add an policy statement similar to the following example to the IAM policy for each WorkSpaces administrator. Replace the example CMK ARN (`arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab`) with a valid one. If your WorkSpaces administrators use only the Amazon WorkSpaces API (not the console), you can omit the second policy statement with the `"kms:ListAliases"` and `"kms:ListKeys"` permissions.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": "kms:CreateGrant",
      "Resource": "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
    },
    {
      "Effect": "Allow",
      "Action": [
        "kms:ListAliases",
        "kms:ListKeys"
      ],
      "Resource": "*"
    }
  ]
}
```

# Monitoring Customer Master Keys

Monitoring is an important part of understanding the availability, state, and usage of your customer master keys (CMKs) in AWS KMS and maintaining the reliability, availability, and performance of your AWS solutions. Collecting monitoring data from all the parts of your AWS solution will help you debug a multipoint failure if one occurs. Before you start monitoring your CMKs, however, create a monitoring plan that includes answers to the following questions:

- What are your monitoring goals?
- What resources will you monitor?
- How often will you monitor these resources?
- What [monitoring tools](#) (p. 286) will you use?
- Who will perform the monitoring tasks?
- Who should be notified when something happens?

The next step is to monitor your CMKs over time to establish a baseline for normal AWS KMS usage and expectations in your environment. As you monitor your CMKs, store historical monitoring data so that you can compare it with current data, identify normal patterns and anomalies, and devise methods to address issues.

For example, you can monitor AWS KMS API activity and events that affect your CMKs. When data falls above or below your established norms, you might need to investigate or take corrective action.

To establish a baseline for normal patterns, monitor the following items:

- AWS KMS API activity for *data plane* operations. These are cryptographic operations that use a CMK, such as [Decrypt](#), [Encrypt](#), [ReEncrypt](#), and [GenerateDataKey](#).
- AWS KMS API activity for *control plane* operations that are important to you. These operations manage a CMK, and you might want to monitor those that change a CMK's availability (such as [ScheduleKeyDeletion](#), [CancelKeyDeletion](#), [DisableKey](#), [EnableKey](#), [ImportKeyMaterial](#), and [DeleteImportedKeyMaterial](#)) or change a CMK's access control (such as [PutKeyPolicy](#) and [RevokeGrant](#)).
- Other AWS KMS metrics (such as the amount of time remaining until your [imported key material](#) (p. 147) expires) and events (such as the expiration of imported key material or the deletion or key rotation of a CMK).

## Monitoring Tools

AWS provides various tools that you can use to monitor your CMKs. You can configure some of these tools to do the monitoring for you, while some of the tools require manual intervention. We recommend that you automate monitoring tasks as much as possible.

### Automated Monitoring Tools

You can use the following automated monitoring tools to watch your CMKs and report when something has changed.

- **Amazon CloudWatch Alarms** – Watch a single metric over a time period that you specify, and perform one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon Simple Notification Service (Amazon SNS) topic or Amazon EC2 Auto Scaling policy. CloudWatch alarms do not invoke actions simply because

they are in a particular state; the state must have changed and been maintained for a specified number of periods. For more information, see [Monitoring with Amazon CloudWatch \(p. 287\)](#).

- **Amazon CloudWatch Events** – Match events and route them to one or more target functions or streams to capture state information and, if necessary, make changes or take corrective action. For more information, see [AWS KMS Events \(p. 290\)](#) and the [Amazon CloudWatch Events User Guide](#).
- **Amazon CloudWatch Logs** – Monitor, store, and access your log files from AWS CloudTrail or other sources. For more information, see the [Amazon CloudWatch Logs User Guide](#).
- **AWS CloudTrail Log Monitoring** – Share log files between accounts, monitor CloudTrail log files in real time by sending them to CloudWatch Logs, write log processing applications with the [CloudTrail Processing Library](#), and validate that your log files have not changed after delivery by CloudTrail. For more information, see [Working with CloudTrail Log Files](#) in the *AWS CloudTrail User Guide*.

## Manual Monitoring Tools

Another important part of monitoring CMKs involves manually monitoring those items that the CloudWatch alarms and events don't cover. The AWS KMS, CloudWatch, AWS Trusted Advisor, and other AWS dashboards provide an at-a-glance view of the state of your AWS environment.

You can [customize \(p. 23\)](#) the **AWS Managed Keys** and **Customer Managed Keys** pages of the [AWS KMS console](#) to display the following information about each CMK:

- Key ID
- Status
- Creation date
- Expiration date (for CMKs with [imported key material \(p. 147\)](#))
- Origin
- Custom key store ID (for CMKs in [custom key stores \(p. 172\)](#))

The [CloudWatch console dashboard](#) shows the following:

- Current alarms and status
- Graphs of alarms and resources
- Service health status

In addition, you can use CloudWatch to do the following:

- Create [customized dashboards](#) to monitor the services you care about
- Graph metric data to troubleshoot issues and discover trends
- Search and browse all your AWS resource metrics
- Create and edit alarms to be notified of problems

AWS Trusted Advisor can help you monitor your AWS resources to improve performance, reliability, security, and cost effectiveness. Four Trusted Advisor checks are available to all users; more than 50 checks are available to users with a Business or Enterprise support plan. For more information, see [AWS Trusted Advisor](#).

## Monitoring with Amazon CloudWatch

You can monitor your customer master keys (CMKs) using Amazon CloudWatch, which collects and processes raw data from AWS KMS into readable, near real-time metrics. These data are recorded for a

period of two weeks so that you can access historical information and gain a better understanding of the usage of your CMKs and their changes over time. For more information about Amazon CloudWatch, see the [Amazon CloudWatch User Guide](#).

#### Topics

- [AWS KMS Metrics and Dimensions \(p. 288\)](#)
- [Creating CloudWatch Alarms to Monitor AWS KMS Metrics \(p. 289\)](#)
- [AWS KMS Events \(p. 290\)](#)

## AWS KMS Metrics and Dimensions

When you [import key material into a CMK \(p. 147\)](#) and set it to expire, AWS KMS sends metrics and dimensions to CloudWatch. You can view the AWS KMS metrics using the AWS Management Console and the Amazon CloudWatch API.

### AWS KMS Metrics

The `AWS/KMS` namespace includes the following metrics.

#### **SecondsUntilKeyMaterialExpiration**

This metric tracks the number of seconds remaining until imported key material expires. This metric is valid only for CMKs whose origin is `EXTERNAL` and whose key material is or was set to expire. The most useful statistic for this metric is `Minimum`, which tells you the smallest amount of time remaining for all data points in the specified statistic period. The only valid unit for this metric is `Seconds`.

Use this metric to track the amount of time that remains until your imported key material expires. When that amount of time falls below a threshold that you define, you might want to take action such as reimporting the key material with a new expiration date. You can create a CloudWatch alarm to notify you when that happens. For more information, see [Creating CloudWatch Alarms to Monitor AWS KMS Metrics \(p. 289\)](#).

### Dimensions for AWS KMS Metrics

AWS KMS metrics use the `AWS/KMS` namespace and have only one valid dimension: `KeyId`. You can use this dimension to view metric data for a specific CMK or set of CMKs.

### How Do I View AWS KMS Metrics?

You can view the AWS KMS metrics using the AWS Management Console and the Amazon CloudWatch API.

#### **To view metrics using the CloudWatch console**

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the region. From the navigation bar, select the region where your AWS resources reside.
3. In the navigation pane, choose **Metrics**.
4. In the content pane, choose the **All metrics** tab. Then, below **AWS Namespaces**, choose **KMS**.
5. Choose **Per-Key Metrics** to view the individual metrics and dimensions.

### To view metrics using the Amazon CloudWatch API

To view AWS KMS metrics using the CloudWatch API, send a [ListMetrics](#) request with `Namespace` set to `AWS/KMS`. The following example shows how to do this with the [AWS Command Line Interface \(AWS CLI\)](#).

```
$ aws cloudwatch list-metrics --namespace AWS/KMS
```

## Creating CloudWatch Alarms to Monitor AWS KMS Metrics

You can create a CloudWatch alarm that sends an Amazon SNS message when the value of the metric changes and causes the alarm to change state. An alarm watches a single metric over a time period you specify, and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. The action is a notification sent to an Amazon SNS topic or Auto Scaling policy. Alarms invoke actions for sustained state changes only. CloudWatch alarms do not invoke actions simply because they are in a particular state; the state must have changed and been maintained for a specified number of periods.

### Topics

- [Create a CloudWatch Alarm to Monitor the Expiration of Imported Key Material \(p. 289\)](#)
- [Create a CloudWatch Alarm to Monitor Usage of CMKs that are Pending Deletion \(p. 290\)](#)

## Create a CloudWatch Alarm to Monitor the Expiration of Imported Key Material

When you [import key material into a CMK \(p. 147\)](#), you can optionally specify a time at which the key material expires. When the key material expires, AWS KMS deletes the key material and the CMK becomes unusable. To use the CMK again, you must reimport key material. You can create a CloudWatch alarm to notify you when the amount of time that remains until your imported key material expires falls below a threshold that you define (for example, 10 days). If you receive a notification from such an alarm, you might want to take action such as reimporting the key material with a new expiration date.

### To create an alarm to monitor the expiration of imported key material (AWS Management Console)

1. Open the CloudWatch console at <https://console.aws.amazon.com/cloudwatch/>.
2. If necessary, change the region. From the navigation bar, select the region where your AWS resources reside.
3. In the navigation pane, choose **Alarms**. Then choose **Create Alarm**.
4. Choose **Browse Metrics** and then choose **KMS**.
5. Select the check box next to the key ID of the CMK to monitor.
6. In the lower pane, use the menus to change the statistic to **Minimum** and the time period to **1 Minute**. Then choose **Next**.
7. In the **Create Alarm** window, do the following:
  - a. For **Name**, type a name such as **KeyMaterialExpiresSoon**.
  - b. Following **Whenever:**, for **is**, choose **<=** and then type the number of seconds for your threshold value. For example, to be notified when the time that remains until your imported key material expires is 10 days or less, type **864000**.
  - c. For **for consecutive period(s)**, if necessary, type **1**.

- d. For **Send notification to:**, do one of the following:
  - To use a new Amazon SNS topic, choose **New list** and then type a new topic name. For **Email list:**, type at least one email address. You can type more than one email address by separating them with commas.
  - To use an existing Amazon SNS topic, choose the name of the topic to use.
- e. Choose **Create Alarm**.

8. If you chose to send notifications to an email address, open the email message you receive from `no-reply@sns.amazonaws.com` with subject "AWS Notification - Subscription Confirmation." Confirm your email address by choosing the **Confirm subscription** link in the email message.

### Important

You will not receive email notifications until after you have confirmed your email address.

## Create a CloudWatch Alarm to Monitor Usage of CMKs that are Pending Deletion

When you [schedule key deletion](#) (p. 160) for a CMK, AWS KMS enforces a waiting period before deleting the CMK. You can use the waiting period to ensure that you don't need the CMK now or in the future. You can also configure a CloudWatch alarm to warn you if a person or application attempts to use the CMK during the waiting period. If you receive a notification from such an alarm, you might want to cancel deletion of the CMK.

For more information, see [Creating an Amazon CloudWatch Alarm to Detect Usage of a Customer Master Key that is Pending Deletion](#) (p. 165).

## AWS KMS Events

AWS KMS integrates with Amazon CloudWatch Events to notify you of certain events that affect your CMKs. Each event is represented in [JSON \(JavaScript Object Notation\)](#) and contains the event name, the

date and time when the event occurred, the CMK affected, and more. You can use CloudWatch Events to collect these events and set up rules that route them to one or more *targets* such as AWS Lambda functions, Amazon SNS topics, Amazon SQS queues, streams in Amazon Kinesis Data Streams, or built-in targets.

For more information about using CloudWatch Events with other kinds of events, including those emitted by AWS CloudTrail when it records a read/write API request, see the [Amazon CloudWatch Events User Guide](#).

The following topics describe the CloudWatch Events that AWS KMS creates.

### Topics

- [KMS CMK Rotation \(p. 291\)](#)
- [KMS Imported Key Material Expiration \(p. 291\)](#)
- [KMS CMK Deletion \(p. 292\)](#)

## KMS CMK Rotation

When you enable [automatic key rotation \(p. 142\)](#) for a [customer managed CMK \(p. 3\)](#), AWS KMS creates new key material for the CMK each year. The key material for [AWS managed CMKs \(p. 4\)](#) is automatically rotated every three years.

Whenever AWS KMS rotates key material, it sends a KMS CMK Rotation event to CloudWatch Events. The following is an example of this event.

```
{
  "version": "0",
  "id": "6a7e8feb-b491-4cf7-a9f1-bf3703467718",
  "detail-type": "KMS CMK Rotation",
  "source": "aws.kms",
  "account": "111122223333",
  "time": "2016-08-25T21:05:33Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
  ],
  "detail": {
    "key-id": "1234abcd-12ab-34cd-56ef-1234567890ab"
  }
}
```

## KMS Imported Key Material Expiration

When you [import key material into a CMK \(p. 147\)](#), you can optionally specify a time at which the key material expires. When the key material expires, AWS KMS deletes the key material and sends a corresponding event to CloudWatch Events. The following is an example of this event.

```
{
  "version": "0",
  "id": "9da9af57-9253-4406-87cb-7cc400e43465",
  "detail-type": "KMS Imported Key Material Expiration",
  "source": "aws.kms",
  "account": "111122223333",
  "time": "2016-08-22T20:12:19Z",
  "region": "us-west-2",
  "resources": [
    "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"
  ],
}
```

```
"detail": {  
  "key-id": "1234abcd-12ab-34cd-56ef-1234567890ab"  
}
```

## KMS CMK Deletion

When you [schedule key deletion \(p. 160\)](#) for a CMK, AWS KMS enforces a waiting period before deleting the CMK. After the waiting period ends, AWS KMS deletes the CMK and sends a corresponding event to CloudWatch Events. The following is an example of this event.

```
{  
  "version": "0",  
  "id": "e9ce3425-7d22-412a-a699-e7a5fc3fbc9a",  
  "detail-type": "KMS CMK Deletion",  
  "source": "aws.kms",  
  "account": "111122223333",  
  "time": "2016-08-19T03:23:45Z",  
  "region": "us-west-2",  
  "resources": [  
    "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab"  
  ],  
  "detail": {  
    "key-id": "1234abcd-12ab-34cd-56ef-1234567890ab"  
  }  
}
```

# Logging AWS KMS API Calls with AWS CloudTrail

AWS KMS is integrated with AWS CloudTrail, a service that provides a record of actions performed by a user, role, or an AWS service in AWS KMS. CloudTrail captures all API calls for AWS KMS as events, including calls from the AWS KMS console and from code calls to the AWS KMS APIs. If you create a trail, you can enable continuous delivery of CloudTrail events to an Amazon S3 bucket, including events for AWS KMS. If you don't configure a trail, you can still view the most recent events in the CloudTrail console in **Event history**. Using the information collected by CloudTrail, you can determine the request that was made to AWS KMS, the IP address from which the request was made, who made the request, when it was made, and additional details.

Although, by default, all AWS KMS actions are logged as CloudTrail events, you can exclude AWS KMS actions from a CloudTrail trail. For details, see [Excluding AWS KMS Events from a Trail \(p. 294\)](#).

To learn more about CloudTrail, see the [AWS CloudTrail User Guide](#). To learn about other ways to monitor the use of your CMKs, see [Monitoring Customer Master Keys \(p. 286\)](#).

## AWS KMS Information in CloudTrail

CloudTrail is enabled on your AWS account when you create the account. When activity occurs in AWS KMS, that activity is recorded in a CloudTrail event along with other AWS service events in **Event history**. You can view, search, and download recent events in your AWS account. For more information, see [Viewing Events with CloudTrail Event History](#).

For an ongoing record of events in your AWS account, including events for AWS KMS, create a trail. A trail enables CloudTrail to deliver log files to an Amazon S3 bucket. By default, when you create a trail in the console, the trail applies to all regions. The trail logs events from all regions in the AWS partition and delivers the log files to the Amazon S3 bucket that you specify. Additionally, you can configure other AWS services to further analyze and act upon the event data collected in CloudTrail logs. For more information, see:

- [Overview for Creating a Trail](#)
- [CloudTrail Supported Services and Integrations](#)
- [Configuring Amazon SNS Notifications for CloudTrail](#)
- [Receiving CloudTrail Log Files from Multiple Regions](#) and [Receiving CloudTrail Log Files from Multiple Accounts](#)

CloudTrail logs all AWS KMS operations, including read-only operations, such as `ListAliases` and `GetKeyPolicy`, operations that manage CMKs, such as `CreateKey` and `PutKeyPolicy`, and cryptographic operations, such as `GenerateDataKey`, `Encrypt`, and `Decrypt`. Every operation generates an entry in the CloudTrail log files.

Every event or log entry contains information about who generated the request. The identity information helps you determine the following:

- Whether the request was made with root or IAM user credentials.
- Whether the request was made with temporary security credentials for a role or federated user.

- Whether the request was made by another AWS service.

For more information, see the [CloudTrail userIdentity Element](#).

## Excluding AWS KMS Events from a Trail

Most AWS KMS users rely on the events in a CloudTrail trail to provide a record of the use and management of their AWS KMS resources. The trail can be an valuable source of data for auditing critical events, such as creating, disabling, and deleting customer master keys (CMKs), changing key policy, and the use of your CMKs by AWS services on your behalf. In some cases, the metadata in a CloudTrail log entry, such as the [encryption context \(p. 12\)](#) in an encryption operation, can help you to avoid or resolve errors.

However, because AWS KMS can generate a large number of events, AWS CloudTrail lets you exclude AWS KMS events from a trail. This per-trail setting excludes all AWS KMS events; you cannot exclude particular AWS KMS events.

### Warning

Excluding AWS KMS events from a CloudTrail Log can obscure actions that use your CMKs. Be cautious when giving principals the `cloudtrail:PutEventSelectors` permission that is required to perform this operation.

To exclude AWS KMS events from a trail:

- In the CloudTrail console, use the **Log Key Management Service events** setting when you [create a trail](#) or [update a trail](#). For instructions, see [Logging Management Events with the AWS Management Console](#) in the AWS CloudTrail User Guide.
- In the CloudTrail API, use the [PutEventSelectors](#) operation. Add the `ExcludeManagementEventSources` attribute to your event selectors with a value of `kms.amazonaws.com`. For an example, see [Example: A trail that does not log AWS Key Management Service events](#) in the AWS CloudTrail User Guide.

You can disable this exclusion at any time by changing the console setting or the event selectors for a trail. The trail will then start recording AWS KMS events. However, it cannot recover AWS KMS events that occurred while the exclusion was effective.

When you exclude KMS events by using the console or API, the resulting CloudTrail `PutEventSelectors` API operation is also logged in your CloudTrail Logs. If KMS events don't appear in your CloudTrail Logs, look for a `PutEventSelectors` event with the `ExcludeManagementEventSources` attribute set to `kms.amazonaws.com`.

## Understanding AWS KMS Log File Entries

A *trail* is a configuration that enables delivery of events as log files to an Amazon S3 bucket that you specify. CloudTrail log files contain one or more log entries. An *event* represents a single request from any source and includes information about the requested action, the date and time of the action, request parameters, and so on. CloudTrail log files are not an ordered stack trace of the public API calls, so they do not appear in any specific order.

For examples CloudTrail log entries for each API request, see the following topics.

## Amazon EC2 Example One

The following example demonstrates an IAM user creating an encrypted volume using the default volume key in the Amazon EC2 management console.

The following example shows a CloudTrail log entry that demonstrates the user Alice creating an encrypted volume using a default volume key in AWS EC2 Management Console. The EC2 log file record includes a `volumeId` field with a value of `"vol-13439757"`. The AWS KMS record contains an `encryptionContext` field with a value of `"aws:ebs:id": "vol-13439757"`. Similarly, the `principalId` and `accountId` between the two records match. The records reflect the fact that creating an encrypted volume generates a data key that is used to encrypt the volume content.

## Amazon EC2 Example Two

The following example shows an IAM user running an Amazon EC2 instance that mounts a data volume encrypted by using a default volume key. The action taken by the user generates multiple AWS KMS log records. Creating the encrypted volume generates a data key, and the Amazon EC2 service generates a grant, on behalf of the customer, that enables it to decrypt the data key. The `instanceId`, "i-81e2f56c", is referred to in the `granteePrincipal` field of the `CreateGrant` record as "123456789012:aws:ec2-infrastructure:i-81e2f56c" as well as in the identity of the principal calling `Decrypt`, "arn:aws:sts::123456789012:assumed-role/aws:ec2-infrastructure/i-81e2f56c". The key identified by the UUID "e29ddfd4-1bf6-4e1b-8ecb-08216bd70d07" is common across all three KMS calls.

# Programming the AWS KMS API

You can use the AWS KMS API to perform the following actions, and more.

- Create, describe, list, enable, and disable keys.
- Create, delete, list, and update aliases.
- Encrypt, decrypt, and re-encrypt content.
- Set, list, and retrieve key policies.
- Create, retire, revoke, and list grants.
- Retrieve key rotation status.
- Update key descriptions.
- Generate data keys with or without plaintext.
- Generate random data.

The sample code in the following topics show how to use the AWS SDKs to call the AWS KMS API.

## Topics

- [Creating a Client \(p. 314\)](#)
- [Working With Keys \(p. 315\)](#)
- [Encrypting and Decrypting Data Keys \(p. 324\)](#)
- [Working with Key Policies \(p. 330\)](#)
- [Working with Grants \(p. 337\)](#)
- [Working with Aliases \(p. 344\)](#)

## Creating a Client

To use the [AWS SDK for Java](#), the [AWS SDK for .NET](#), the [AWS SDK for Python \(Boto 3\)](#), the [AWS SDK for Ruby](#), the [AWS SDK for PHP](#), or the [AWS SDK for JavaScript in Node.js](#) to write code that uses the [AWS Key Management Service \(AWS KMS\) API](#), start by creating an AWS KMS client.

The client object that you create is used in the example code in the topics that follow.

### Java

To create an AWS KMS client in Java, use the client builder.

```
AWSKMS kmsClient = AWSKMSClientBuilder.standard().build();
```

For more information about using the Java client builder, see the following resources.

- [Fluent Client Builders](#) on the AWS Developer Blog
- [Creating Service Clients](#) in the *AWS SDK for Java Developer Guide*
- [AWSKMSClientBuilder](#) in the *AWS SDK for Java API Reference*

### C#

```
AmazonKeyManagementServiceClient kmsClient = new AmazonKeyManagementServiceClient();
```

#### Python

```
kms_client = boto3.client('kms')
```

#### Ruby

```
require 'aws-sdk-kms' # in v2: require 'aws-sdk'

kmsClient = Aws::KMS::Client.new
```

#### PHP

To create an AWS KMS client in PHP, use an AWS KMS client object, and specify version 2014-11-01. For more information see the [KMSSClient class](#) in the AWS SDK for PHP API Reference.

```
// Create a KMSSClient
$KmsClient = new Aws\Kms\KmsClient([
    'profile' => 'default',
    'version' => '2014-11-01',
    'region'  => 'us-east-1'
]);
```

#### Node.js

```
const kmsClient = new AWS.KMS();
```

## Working With Keys

The examples in this topic use the AWS KMS API to create, view, enable, and disable AWS KMS customer master keys, and to generate data keys.

#### Topics

- [Creating a Customer Master Key \(p. 315\)](#)
- [Generating a Data Key \(p. 317\)](#)
- [Viewing a Custom Master Key \(p. 319\)](#)
- [Getting Key IDs and Key ARNs of Customer Master Keys \(p. 320\)](#)
- [Enabling Customer Master Keys \(p. 321\)](#)
- [Disabling Customer Master Keys \(p. 323\)](#)

## Creating a Customer Master Key

To create a [customer master key \(p. 2\)](#), use the [CreateKey](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [createKey method](#) in the *AWS SDK for Java API Reference*.

```
// Create a CMK
//
String desc = "Key for protecting critical data";
```

```
CreateKeyRequest req = new CreateKeyRequest().withDescription(desc);  
CreateKeyResult result = kmsClient.createKey(req);
```

## C#

For details, see the [CreateKey method](#) in the *AWS SDK for .NET*.

```
// Create a CMK  
//  
String desc = "Key for protecting critical data";  
  
CreateKeyRequest req = new CreateKeyRequest()  
{  
    Description = desc  
};  
CreateKeyResponse response = kmsClient.CreateKey(req);
```

## Python

For details, see the [create\\_key method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Create a CMK  
  
desc = 'Key for protecting critical data'  
  
response = kms_client.create_key(  
    Description=desc  
)
```

## Ruby

For details, see the [create\\_key](#) instance method in the *AWS SDK for Ruby*.

```
# Create a CMK  
  
desc = 'Key for protecting critical data'  
  
response = kmsClient.create_key({  
    description: desc  
})
```

## PHP

For details, see the [CreateKey method](#) in the *AWS SDK for PHP*.

```
// Create a CMK  
//  
$desc = "Key for protecting critical data";  
  
$result = $KmsClient->createKey([  
    'Description' => $desc  
]);
```

## Node.js

For details, see the [createKey property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Create a CMK  
//  
const Description = 'Key for protecting critical data';
```

```
kmsClient.createKey({ Description }, (err, data) => {  
    ...  
});
```

## Generating a Data Key

To generate a data key, use the [GenerateDataKey](#) operation. This operation returns plaintext and encrypted copies of the data key that it creates.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

### Java

For details, see the [generateDataKey](#) method in the *AWS SDK for Java API Reference*.

```
// Generate a data key  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
GenerateDataKeyRequest dataKeyRequest = new GenerateDataKeyRequest();  
dataKeyRequest.setKeyId(keyId);  
dataKeyRequest.setKeySpec("AES_256");  
  
GenerateDataKeyResult dataKeyResult = kmsClient.generateDataKey(dataKeyRequest);  
  
ByteBuffer plaintextKey = dataKeyResult.getPlaintext();  
  
ByteBuffer encryptedKey = dataKeyResult.getCiphertextBlob();
```

### C#

For details, see the [GenerateDataKey](#) method in the *AWS SDK for .NET*.

```
// Generate a data key  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
GenerateDataKeyRequest dataKeyRequest = new GenerateDataKeyRequest()  
{  
    KeyId = keyId,  
    KeySpec = DataKeySpec.AES_256  
};  
  
GenerateDataKeyResponse dataKeyResponse = kmsClient.GenerateDataKey(dataKeyRequest);  
  
MemoryStream plaintextKey = dataKeyResponse.Plaintext;  
  
MemoryStream encryptedKey = dataKeyResponse.CiphertextBlob;
```

### Python

For details, see the [generate\\_date\\_key](#) method in the AWS SDK for Python (Boto 3).

```
# Generate a data key  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
```

```
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kms_client.generate_data_key(
    KeyId=key_id,
    KeySpec='AES_256'
)

plaintext_key = response['Plaintext']

encrypted_key = response['CiphertextBlob']
```

## Ruby

For details, see the [generate\\_data\\_key](#) instance method in the [AWS SDK for Ruby](#).

```
# Generate a data key

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.generate_data_key({
  key_id: key_id,
  key_spec: 'AES_256'
})

plaintextKey = response.plaintext

encryptedKey = response.ciphertext_blob
```

## PHP

For details, see the [GenerateDataKey](#) method in the [AWS SDK for PHP](#).

```
// Generate a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
$keySpec = 'AES_256';

$result = $KmsClient->generateDataKey([
    'KeyId' => $keyId,
    'KeySpec' => $keySpec,
]);

$plaintextKey = $result['Plaintext'];

$encryptedKey = $result['CiphertextBlob'];
```

## Node.js

For details, see the [generateDataKey](#) property in the [AWS SDK for JavaScript in Node.js](#).

```
// Generate a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
const KeySpec = 'AES_256';
kmsClient.generateDataKey({ KeyId, KeySpec }, (err, data) => {
  if (err) console.log(err, err.stack);
  else {
    const { CiphertextBlob, Plaintext } = data;
```

```
    }  
    ...  
  }  
};
```

## Viewing a Custom Master Key

To get detailed information about a customer master key (CMK), including the CMK ARN and [key state](#) (p. 223), use the [DescribeKey](#) operation.

DescribeKey does not get aliases. To get aliases, use the [ListAliases](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client](#) (p. 314).

### Java

For details, see the [describeKey method](#) in the *AWS SDK for Java API Reference*.

```
// Describe a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
DescribeKeyRequest req = new DescribeKeyRequest().withKeyId(keyId);  
DescribeKeyResult result = kmsClient.describeKey(req);
```

### C#

For details, see the [DescribeKey method](#) in the *AWS SDK for .NET*.

```
// Describe a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
DescribeKeyRequest describeKeyRequest = new DescribeKeyRequest()  
{  
    KeyId = keyId  
};  
  
DescribeKeyResponse describeKeyResponse = kmsClient.DescribeKey(describeKeyRequest);
```

### Python

For details, see the [describe\\_key method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Describe a CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
response = kms_client.describe_key(  
    KeyId=key_id  
)
```

### Ruby

For details, see the [describe\\_key](#) instance method in the *AWS SDK for Ruby*.

```
# Describe a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.describe_key({
    key_id: keyId
})
```

#### PHP

For details, see the [DescribeKey method](#) in the *AWS SDK for PHP*.

```
// Describe a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';

$result = $KmsClient->describeKey([
    'KeyId' => $keyId,
]);
```

#### Node.js

For details, see the [describeKey property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Describe a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
kmsClient.describeKey({ KeyId }, (err, data) => {
    ...
});
```

## Getting Key IDs and Key ARNs of Customer Master Keys

To get the IDs and ARNs of the customer master keys, use the [ListKeys](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [listKeys method](#) in the *AWS SDK for Java API Reference*.

```
// List CMKs in this account
//
Integer limit = 10;

ListKeysRequest req = new ListKeysRequest().withLimit(limit);
ListKeysResult result = kmsClient.listKeys(req);
```

#### C#

For details, see the [ListKeys method](#) in the *AWS SDK for .NET*.

```
// List CMKs in this account
//
int limit = 10;

ListKeysRequest listKeysRequest = new ListKeysRequest()
{
    Limit = limit
};
ListKeysResponse listKeysResponse = kmsClient.ListKeys(listKeysRequest);
```

### Python

For details, see the [list\\_keys method](#) in the AWS SDK for Python (Boto 3).

```
# List CMKs in this account

response = kms_client.list_keys(
    Limit=10
)
```

### Ruby

For details, see the [list\\_keys](#) instance method in the [AWS SDK for Ruby](#).

```
# List CMKS in this account

response = kmsClient.list_keys({
  limit: 10
})
```

### PHP

For details, see the [ListKeys method](#) in the *AWS SDK for PHP*.

```
// List CMKs in this account
//
$limit = 10;

$result = $KmsClient->listKeys([
    'Limit' => $limit,
]);
```

### Node.js

For details, see the [listKeys property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// List CMKs in this account
//
const Limit = 10;
kmsClient.listKeys({ Limit }, (err, data) => {
    ...
});
```

## Enabling Customer Master Keys

To enable a disabled customer master key (CMK), use the [EnableKey](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

## Java

For details about the Java implementation, see the [enableKey method](#) in the *AWS SDK for Java API Reference*.

```
// Enable a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

EnableKeyRequest req = new EnableKeyRequest().withKeyId(keyId);
kmsClient.enableKey(req);
```

## C#

For details, see the [EnableKey method](#) in the *AWS SDK for .NET*.

```
// Enable a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

EnableKeyRequest enableKeyRequest = new EnableKeyRequest()
{
    KeyId = keyId
};
kmsClient.EnableKey(enableKeyRequest);
```

## Python

For details, see the [enable\\_key method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Enable a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kms_client.enable_key(
    KeyId=key_id
)
```

## Ruby

For details, see the [enable\\_key](#) instance method in the *AWS SDK for Ruby*.

```
# Enable a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.enable_key({
  key_id: keyId
})
```

## PHP

For details, see the [EnableKey method](#) in the *AWS SDK for PHP*.

```
// Enable a CMK
```

```
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
  
$result = $KmsClient->enableKey([  
    'KeyId' => $keyId,  
]);
```

#### Node.js

For details, see the [enableKey property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Enable a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
kmsClient.enableKey({ KeyId }, (err, data) => {  
    ...  
});
```

## Disabling Customer Master Keys

To disable a CMK, use the [DisableKey](#) operation. Disabling a CMK prevents it from being used.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [disableKey method](#) in the *AWS SDK for Java API Reference*.

```
// Disable a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
DisableKeyRequest req = new DisableKeyRequest().withKeyId(keyId);  
kmsClient.disableKey(req);
```

#### C#

For details, see the [DisableKey method](#) in the *AWS SDK for .NET*.

```
// Disable a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
DisableKeyRequest disableKeyRequest = new DisableKeyRequest()  
{  
    KeyId = keyId  
};  
kmsClient.DisableKey(disableKeyRequest);
```

#### Python

For details, see the [disable\\_key method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Disable a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kms_client.disable_key(
    KeyId=key_id
)
```

## Ruby

For details, see the [disable\\_key](#) instance method in the [AWS SDK for Ruby](#).

```
# Disable a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.disable_key({
  key_id: keyId
})
```

## PHP

For details, see the [DisableKey](#) method in the [AWS SDK for PHP](#).

```
// Disable a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';

$result = $KmsClient->disableKey([
    'KeyId' => $keyId,
]);
```

## Node.js

For details, see the [disableKey](#) property in the [AWS SDK for JavaScript in Node.js](#).

```
// Disable a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
kmsClient.disableKey({ KeyId }, (err, data) => {
    ...
});
```

# Encrypting and Decrypting Data Keys

The examples in this topic use the [Encrypt](#), [Decrypt](#), and [ReEncrypt](#) operations in the AWS KMS API.

These operations are designed to encrypt and decrypt [data keys](#) (p. 4). They use an AWS KMS [customer master key](#) (p. 2) (CMK) in the encryption operations and they cannot accept more than 4 KB (4096 bytes) of data. Although you might use them to encrypt small amounts of data, such as a password or RSA key, they are not designed to encrypt application data.

To encrypt application data, use the server-side encryption features of an AWS service, or a client-side encryption library, such as the [AWS Encryption SDK](#) or the [Amazon S3 encryption client](#).

### Topics

- [Encrypting a Data Key](#) (p. 325)
- [Decrypting a Data Key](#) (p. 327)
- [Re-Encrypting a Data Key Under a Different Customer Master Key](#) (p. 328)

## Encrypting a Data Key

The [Encrypt](#) operation is designed to encrypt data keys, but it is not frequently used. The [GenerateDataKey](#) and [GenerateDataKeyWithoutPlaintext](#) operations return encrypted data keys. You might use this method when you are moving encrypted data to a new region and want to encrypt its data key with a CMK in the new region.

This example uses the AWS KMS client object that you created in [Creating a Client](#) (p. 314).

### Java

For details, see the [encrypt method](#) in the *AWS SDK for Java API Reference*.

```
// Encrypt a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
ByteBuffer plaintext = ByteBuffer.wrap(new byte[] {1,2,3,4,5,6,7,8,9,0});

EncryptRequest req = new EncryptRequest().withKeyId(keyId).withPlaintext(plaintext);
ByteBuffer ciphertext = kmsClient.encrypt(req).getCiphertextBlob();
```

### C#

For details, see the [Encrypt method](#) in the *AWS SDK for .NET*.

```
// Encrypt a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
MemoryStream plaintext = new MemoryStream();
plaintext.Write(new byte[] { 1, 2, 3, 4, 5, 6, 7, 8, 9, 0 }, 0, 10);

EncryptRequest encryptRequest = new EncryptRequest()
{
    KeyId = keyId,
    Plaintext = plaintext
};
MemoryStream ciphertext = kmsClient.Encrypt(encryptRequest).CiphertextBlob;
```

### Python

For details, see the [encrypt method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Encrypt a data key

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
```

```
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
plaintext = b'\x01\x02\x03\x04\x05\x06\x07\x08\x09\x00'

response = kms_client.encrypt(
    KeyId=key_id,
    Plaintext=plaintext
)

ciphertext = response['CiphertextBlob']
```

## Ruby

For details, see the [encrypt](#) instance method in the [AWS SDK for Ruby](#).

```
# Encrypt a data key

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
plaintext = "\x01\x02\x03\x04\x05\x06\x07\x08\x09\x00"

response = kmsClient.encrypt({
  key_id: keyId,
  plaintext: plaintext
})

ciphertext = response.ciphertext_blob
```

## PHP

For details, see the [Encrypt method](#) in the [AWS SDK for PHP](#).

```
// Encrypt a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
$message = pack('C*', 1, 2, 3, 4, 5, 6, 7, 8, 9, 0);

$result = $KmsClient->encrypt([
    'KeyId' => $keyId,
    'Plaintext' => $message,
]);

$ciphertext = $result['CiphertextBlob'];
```

## Node.js

For details, see the [encrypt property](#) in the [AWS SDK for JavaScript in Node.js](#).

```
// Encrypt a data key
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
const Plaintext = Buffer.from([1, 2, 3, 4, 5, 6, 7, 8, 9, 0]);
kmsClient.encrypt({ KeyId, Plaintext }, (err, data) => {
  if (err) console.log(err, err.stack); // an error occurred
  else {
    const { CiphertextBlob } = data;
    ...
  }
});
```

## Decrypting a Data Key

To decrypt a data key, use the [Decrypt](#) operation.

The `ciphertextBlob` that you specify must be the value of the `CiphertextBlob` field from a [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), or [Encrypt](#) response.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

### Java

For details, see the [decrypt method](#) in the *AWS SDK for Java API Reference*.

```
// Decrypt a data key
//

ByteBuffer ciphertextBlob = Place your ciphertext here;

DecryptRequest req = new DecryptRequest().withCiphertextBlob(ciphertextBlob);
ByteBuffer plainText = kmsClient.decrypt(req).getPlaintext();
```

### C#

For details, see the [Decrypt method](#) in the *AWS SDK for .NET*.

```
// Decrypt a data key
//

MemoryStream ciphertextBlob = new MemoryStream();
// Write ciphertext to memory stream

DecryptRequest decryptRequest = new DecryptRequest()
{
    CiphertextBlob = ciphertextBlob
};
MemoryStream plainText = kmsClient.Decrypt(decryptRequest).Plaintext;
```

### Python

For details, see the [decrypt method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Decrypt a data key

ciphertext = 'Place your ciphertext here'

response = kms_client.decrypt(
    CiphertextBlob=ciphertext
)

plaintext = response['Plaintext']
```

### Ruby

For details, see the [decrypt](#) instance method in the *AWS SDK for Ruby*.

```
# Decrypt a data key

ciphertext = 'Place your ciphertext here'
ciphertext_packed = [ciphertext].pack("H*")
```

```
response = kmsClient.decrypt({
  ciphertext_blob: ciphertext_packed
})

plaintext = response.plaintext
```

#### PHP

For details, see the [Decrypt method](#) in the *AWS SDK for PHP*.

```
// Decrypt a data key
//
$ciphertext = 'Place your cipher text blob here';

$result = $KmsClient->decrypt([
  'CiphertextBlob' => $ciphertext
]);

$plaintext = $result['Plaintext'];
```

#### Node.js

For details, see the [decrypt property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Decrypt a data key
//
const CiphertextBlob = 'Place your cipher text blob here';
kmsClient.decrypt({ CiphertextBlob }, (err, data) => {
  if (err) console.log(err, err.stack); // an error occurred
  else {
    const { Plaintext } = data;
    ...
  }
});
```

## Re-Encrypting a Data Key Under a Different Customer Master Key

To decrypt an encrypted data key, and then immediately re-encrypt the data key under a different customer master key (CMK), use the [ReEncrypt](#) operation. The operations are performed entirely on the server side within AWS KMS, so they never expose your plaintext outside of AWS KMS.

The `ciphertextBlob` that you specify must be the value of the `CiphertextBlob` field from a [GenerateDataKey](#), [GenerateDataKeyWithoutPlaintext](#), or [Encrypt](#) response.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [reEncrypt method](#) in the *AWS SDK for Java API Reference*.

```
// Re-encrypt a data key

ByteBuffer sourceCiphertextBlob = Place your ciphertext here;

// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
```

```
String destinationKeyId = "arn:aws:kms:us-  
west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321";  
  
ReEncryptRequest req = new ReEncryptRequest();  
req.setCiphertextBlob(sourceCiphertextBlob);  
req.setDestinationKeyId(destinationKeyId);  
ByteBuffer destinationCipherTextBlob = kmsClient.reEncrypt(req).getCiphertextBlob();
```

## C#

For details, see the [ReEncrypt method](#) in the *AWS SDK for .NET*.

```
// Re-encrypt a data key  
  
MemoryStream sourceCiphertextBlob = new MemoryStream();  
// Write ciphertext to memory stream  
  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String destinationKeyId = "arn:aws:kms:us-  
west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321";  
  
ReEncryptRequest reEncryptRequest = new ReEncryptRequest()  
{  
    CiphertextBlob = sourceCiphertextBlob,  
    DestinationKeyId = destinationKeyId  
};  
MemoryStream destinationCipherTextBlob =  
    kmsClient.ReEncrypt(reEncryptRequest).CiphertextBlob;
```

## Python

For details, see the [re\\_encrypt method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Re-encrypt a data key  
ciphertext = 'Place your ciphertext here'  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
key_id = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'  
  
response = kms_client.re_encrypt(  
    CiphertextBlob=ciphertext,  
    DestinationKeyId=key_id  
)  
  
destination_ciphertext_blob = response['CiphertextBlob']
```

## Ruby

For details, see the [re\\_encrypt](#) instance method in the *AWS SDK for Ruby*.

```
# Re-encrypt a data key  
  
ciphertext = 'Place your ciphertext here'  
ciphertext_packed = [ciphertext].pack("H*")  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
keyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'  
  
response = kmsClient.re_encrypt({  
    ciphertext_blob: ciphertext_packed,  
    destination_key_id: keyId
```

```
    })  
  
    destination_ciphertext_blob = response.ciphertext_blob.unpack('H*')
```

#### PHP

For details, see the [ReEncrypt method](#) in the *AWS SDK for PHP*.

```
// Re-encrypt a data key  
  
$ciphertextBlob = 'Place your ciphertext here';  
  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321';  
  
$result = $KmsClient->reEncrypt([  
    'CiphertextBlob' => $ciphertextBlob,  
    'DestinationKeyId' => $keyId,  
]);
```

#### Node.js

For details, see the [reEncrypt property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Re-encrypt a data key  
const CiphertextBlob = 'Place your cipher text blob here';  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const DestinationKeyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321';  
kmsClient.reEncrypt({ CiphertextBlob, DestinationKeyId }, (err, data) => {  
    ...  
});
```

## Working with Key Policies

The examples in this topic use the AWS KMS API to view and change the key policies of AWS KMS customer master keys (CMKs). For details about how to use key policies and IAM policies to manage access to your CMKs, see [Authentication and Access Control for AWS KMS \(p. 46\)](#).

#### Topics

- [Listing Key Policy Names \(p. 330\)](#)
- [Getting a Key Policy \(p. 332\)](#)
- [Setting a Key Policy \(p. 334\)](#)

### Listing Key Policy Names

To get the names of key policies for a customer master key, use the [ListKeyPolicies](#) operation. The only key policy name it returns is **default**.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details about the Java implementation, see the [listKeyPolicies method](#) in the *AWS SDK for Java API Reference*.

```
// List key policies
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

ListKeyPoliciesRequest req = new ListKeyPoliciesRequest().withKeyId(keyId);
ListKeyPoliciesResult result = kmsClient.listKeyPolicies(req);
```

## C#

For details, see the [ListKeyPolicies method](#) in the *AWS SDK for .NET*.

```
// List key policies
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

ListKeyPoliciesRequest listKeyPoliciesRequest = new ListKeyPoliciesRequest()
{
    KeyId = keyId
};
ListKeyPoliciesResponse listKeyPoliciesResponse =
    kmsClient.ListKeyPolicies(listKeyPoliciesRequest);
```

## Python

For details, see the [list\\_key\\_policies method](#) in the *AWS SDK for Python (Boto 3)*.

```
# List key policies

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kms_client.list_key_policies(
    KeyId=key_id
)
```

## Ruby

For details, see the [list\\_key\\_policies](#) instance method in the *AWS SDK for Ruby*.

```
# List key policies

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.list_key_policies({
  key_id: keyId
})
```

## PHP

For details, see the [ListKeyPolicies method](#) in the *AWS SDK for PHP*.

```
// List key policies
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
```

```
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
  
$result = $KmsClient->listKeyPolicies([  
    'KeyId' => $keyId  
]);
```

#### Node.js

For details, see the [listKeyPolicies property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// List key policies  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const KeyId = 'arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
  
kmsClient.listKeyPolicies({ KeyId }, (err, data) => {  
    ...  
});
```

## Getting a Key Policy

To get the key policy for a customer master key, use the [GetKeyPolicy](#) operation.

[GetKeyPolicy](#) requires a policy name. The only valid policy name is **default**.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [getKeyPolicy method](#) in the *AWS SDK for Java API Reference*.

```
// Get the policy for a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
String policyName = "default";  
  
GetKeyPolicyRequest req = new  
    GetKeyPolicyRequest().withKeyId(keyId).withPolicyName(policyName);  
GetKeyPolicyResult result = kmsClient.getKeyPolicy(req);
```

#### C#

For details, see the [GetKeyPolicy method](#) in the *AWS SDK for .NET*.

```
// Get the policy for a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
String policyName = "default";  
  
GetKeyPolicyRequest getKeyPolicyRequest = new GetKeyPolicyRequest()  
{  
    KeyId = keyId,  
    PolicyName = policyName  
};
```

```
GetKeyPolicyResponse getKeyPolicyResponse =  
    kmsClient.GetKeyPolicy(getKeyPolicyRequest);
```

## Python

For details, see the [get\\_key\\_policy method](#) in the AWS SDK for Python (Boto 3).

```
# Get the policy for a CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
policy_name = 'default'  
  
response = kms_client.get_key_policy(  
    KeyId=key_id,  
    PolicyName=policy_name  
)
```

## Ruby

For details, see the [get\\_key\\_policy](#) instance method in the [AWS SDK for Ruby](#).

```
# Get the policy for a CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
policyName = 'default'  
  
response = kmsClient.get_key_policy({  
    key_id: keyId,  
    policy_name: policyName  
})
```

## PHP

For details, see the [GetKeyPolicy method](#) in the *AWS SDK for PHP*.

```
// Get the policy for a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
$policyName = "default";  
  
$result = $KmsClient->getKeyPolicy([  
    'KeyId' => $keyId,  
    'PolicyName' => $policyName  
]);
```

## Node.js

For details, see the [getKeyPolicy property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Get the policy for a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
const PolicyName = 'default';  
kmsClient.getKeyPolicy({ KeyId, PolicyName }, (err, data) => {  
    ...  
});
```

## Setting a Key Policy

To establish or change a key policy for a CMK, use the [PutKeyPolicy](#) operation.

PutKeyPolicy requires a policy name. The only valid policy name is **default**.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

### Java

For details, see the [putKeyPolicy method](#) in the *AWS SDK for Java API Reference*.

```
// Set a key policy for a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
String policyName = "default";
String policy = "{" +
    "  \"Version\": \"2012-10-17\"," +
    "  \"Statement\": [{\" +
    "    \"Sid\": \"Allow access for ExampleUser\"," +
    "    \"Effect\": \"Allow\"," +
    // Replace the following user ARN with one for a real user.
    "    \"Principal\": {\"AWS\": \"arn:aws:iam::111122223333:user/
ExampleUser\"}," +
    "    \"Action\": [\" +
    "      \"kms:Encrypt\"," +
    "      \"kms:GenerateDataKey*\",\" +
    "      \"kms:Decrypt\"," +
    "      \"kms:DescribeKey\"," +
    "      \"kms:ReEncrypt*\"" +
    "    ],\" +
    "    \"Resource\": \"*\"" +
    "  }]" +
    "}";

PutKeyPolicyRequest req = new
    PutKeyPolicyRequest().withKeyId(keyId).withPolicy(policy).withPolicyName(policyName);
kmsClient.putKeyPolicy(req);
```

### C#

For details, see the [PutKeyPolicy method](#) in the *AWS SDK for .NET*.

```
// Set a key policy for a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
String policyName = "default";
String policy = "{" +
    "  \"Version\": \"2012-10-17\"," +
    "  \"Statement\": [{\" +
    "    \"Sid\": \"Allow access for ExampleUser\"," +
    "    \"Effect\": \"Allow\"," +
    // Replace the following user ARN with one for a real user.
    "    \"Principal\": {\"AWS\": \"arn:aws:iam::111122223333:user/
ExampleUser\"}," +
    "    \"Action\": [\" +
    "      \"kms:Encrypt\"," +
    "      \"kms:GenerateDataKey*\",\" +
    "      \"kms:Decrypt\"," +
```

```

        "        \"kms:DescribeKey\", \" +
        "        \"kms:ReEncrypt*\" \" +
        "    ], \" +
        "    \"Resource\": \"*\" \" +
        "    }]" +
        "};

PutKeyPolicyRequest putKeyPolicyRequest = new PutKeyPolicyRequest()
{
    KeyId = keyId,
    Policy = policy,
    PolicyName = policyName
};
kmsClient.PutKeyPolicy(putKeyPolicyRequest);

```

## Python

For details, see the [put\\_key\\_policy method](#) in the AWS SDK for Python (Boto 3).

```

# Set a key policy for a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
policy_name = 'default'
policy = """

```

## PHP

For details, see the [PutKeyPolicy method](#) in the *AWS SDK for PHP*.

```

// Set a key policy for a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
$policyName = "default";

$result = $KmsClient->putKeyPolicy([
    'KeyId' => $keyId,
    'PolicyName' => $policyName,
    'Policy' => '{
        "Version": "2012-10-17",
        "Id": "custom-policy-2016-12-07",
        "Statement": [
            { "Sid": "Enable IAM User Permissions",
              "Effect": "Allow",
              "Principal":
                { "AWS": "arn:aws:iam::111122223333:user/root" },
              "Action": [ "kms:*" ],
              "Resource": "*" },
            { "Sid": "Enable IAM User Permissions",
              "Effect": "Allow",
              "Principal":
                { "AWS": "arn:aws:iam::111122223333:user/ExampleUser" },
              "Action": [
                  "kms:Encrypt*",
                  "kms:GenerateDataKey*",
                  "kms:Decrypt*",
                  "kms:DescribeKey*",
                  "kms:ReEncrypt*"
                ],
              "Resource": "*" }
        ]
    }'
]);

```

## Node.js

For details, see the [putKeyPolicy property](#) in the *AWS SDK for Node.js*.

```

// Set a key policy for a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN

```

```
const KeyId = 'arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
const PolicyName = 'default';  
const Policy = `{  
  "Version": "2012-10-17",  
  "Id": "custom-policy-2016-12-07",  
  "Statement": [  
    {  
      "Sid": "Enable IAM User Permissions",  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "arn:aws:iam::111122223333:root"  
      },  
      "Action": "kms:*",  
      "Resource": "*"   
    },  
    {  
      "Sid": "Enable IAM User Permissions",  
      "Effect": "Allow",  
      "Principal": {  
        "AWS": "arn:aws:iam::111122223333:user/ExampleUser"  
      },  
      "Action": [  
        "kms:Encrypt*",  
        "kms:GenerateDataKey*",  
        "kms:Decrypt*",  
        "kms:DescribeKey*",  
        "kms:ReEncrypt*"   
      ],  
      "Resource": "*"   
    }  
  ]  
}; // The key policy document  
  
kmsClient.putKeyPolicy({ KeyId, Policy, PolicyName }, (err, data) => {  
  ...  
});
```

## Working with Grants

The examples in this topic use the AWS KMS API to create, view, retire, and revoke grants on AWS KMS customer master keys (CMKs).

### Topics

- [Creating a Grant \(p. 337\)](#)
- [Viewing a Grant \(p. 339\)](#)
- [Retiring a Grant \(p. 341\)](#)
- [Revoking a Grant \(p. 342\)](#)

## Creating a Grant

To create a grant for an AWS KMS customer master key, use the [CreateGrant](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

### Java

For details, see the [createGrant method](#) in the *AWS SDK for Java API Reference*.

```
// Create a grant
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
String granteePrincipal = "arn:aws:iam::111122223333:user/Alice";
String operation = GrantOperation.GenerateDataKey.toString();

CreateGrantRequest request = new CreateGrantRequest()
    .withKeyId(keyId)
    .withGranteePrincipal(granteePrincipal)
    .withOperations(operation);

CreateGrantResult result = kmsClient.createGrant(request);
```

## C#

For details, see the [CreateGrant method](#) in the *AWS SDK for .NET*.

```
// Create a grant
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
String granteePrincipal = "arn:aws:iam::111122223333:user/Alice";
String operation = GrantOperation.GenerateDataKey;

CreateGrantRequest createGrantRequest = new CreateGrantRequest()
{
    KeyId = keyId,
    GranteePrincipal = granteePrincipal,
    Operations = new List<string>() { operation }
};

CreateGrantResponse createGrantResult = kmsClient.CreateGrant(createGrantRequest);
```

## Python

For details, see the [create\\_grant method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Create a grant

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
grantee_principal = 'arn:aws:iam::111122223333:user/Alice'
operation = ['GenerateDataKey']

response = kms_client.create_grant(
    KeyId=key_id,
    GranteePrincipal=grantee_principal,
    Operations=operation
)
```

## Ruby

For details, see the [create\\_grant](#) instance method in the *AWS SDK for Ruby*.

```
# Create a grant

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
granteePrincipal = 'arn:aws:iam::111122223333:user/Alice'
```

```
operation = ['GenerateDataKey']

response = kmsClient.create_grant({
    key_id: keyId,
    grantee_principal: granteePrincipal,
    operations: operation
})
```

## PHP

For details, see the [CreateGrant method](#) in the *AWS SDK for PHP*.

```
// Create a grant
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
$granteePrincipal = "arn:aws:iam::111122223333:user/Alice";
$operation = ['GenerateDataKey']

$result = $KmsClient->createGrant([
    'GranteePrincipal' => $granteePrincipal,
    'KeyId' => $keyId,
    'Operations' => $operation
]);
```

## Node.js

For details, see the [createGrant property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Create a grant
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
const GranteePrincipal = 'arn:aws:iam::111122223333:user/Alice';
const Operations = ["GenerateDataKey"];
kmsClient.createGrant({ KeyId, GranteePrincipal, Operations }, (err, data) => {
    ...
});
```

# Viewing a Grant

To get detailed information about the grants on an AWS KMS customer master key, use the [ListGrants](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

## Java

For details about the Java implementation, see the [listGrants method](#) in the *AWS SDK for Java API Reference*.

```
// Listing grants on a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
Integer limit = 10;
```

```
ListGrantsRequest req = new ListGrantsRequest().withKeyId(keyId).withLimit(limit);  
ListGrantsResult result = kmsClient.listGrants(req);
```

## C#

For details, see the [ListGrants method](#) in the *AWS SDK for .NET*.

```
// Listing grants on a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
int limit = 10;  
  
ListGrantsRequest listGrantsRequest = new ListGrantsRequest()  
{  
    KeyId = keyId,  
    Limit = limit  
};  
ListGrantsResponse listGrantsResponse = kmsClient.ListGrants(listGrantsRequest);
```

## Python

For details, see the [list\\_grants method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Listing grants on a CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
response = kms_client.list_grants(  
    KeyId=key_id,  
    Limit=10  
)
```

## Ruby

For details, see the [list\\_grants](#) instance method in the *AWS SDK for Ruby*.

```
# Listing grants on a CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
response = kmsClient.list_grants({  
    key_id: keyId,  
    limit: 10  
})
```

## PHP

For details, see the [ListGrants method](#) in the *AWS SDK for PHP*.

```
// Listing grants on a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
$limit = 10;  
  
$result = $KmsClient->listGrants([  
    'KeyId' => $keyId,
```

```
    'Limit' => $limit,  
  ]);
```

#### Node.js

For details, see the [listGrants property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Listing grants on a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const KeyId = 'arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
const Limit = 10;  
kmsClient.listGrants({ KeyId, Limit }, (err, data) => {  
    ...  
});
```

## Retiring a Grant

To retire a grant for an AWS KMS customer master key, use the [RetireGrant](#) operation. You should retire a grant to clean up after you are done using it.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [retireGrant method](#) in the *AWS SDK for Java API Reference*.

```
// Retire a grant  
//  
String grantToken = Place your grant token here;  
  
RetireGrantRequest req = new RetireGrantRequest().withGrantToken(grantToken);  
kmsClient.retireGrant(req);
```

#### C#

For details, see the [RetireGrant method](#) in the *AWS SDK for .NET*.

```
// Retire a grant  
//  
String grantToken = "Place your grant token here";  
  
RetireGrantRequest retireGrantRequest = new RetireGrantRequest()  
{  
    GrantToken = grantToken  
};  
kmsClient.RetireGrant(retireGrantRequest);
```

#### Python

For details, see the [retire\\_grant method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Retire a grant  
  
grant_token = Place your grant token here  
  
response = kms_client.retire_grant(  

```

```
    GrantToken=grant_token  
  )  
}
```

## Ruby

For details, see the [retire\\_grant](#) instance method in the [AWS SDK for Ruby](#).

```
# Retire a grant  
  
grantToken = Place your grant token here  
  
response = kmsClient.retire_grant({  
  grant_token: grantToken  
})
```

## PHP

For details, see the [RetireGrant](#) method in the [AWS SDK for PHP](#).

```
// Retire a grant  
//  
$grantToken = 'Place your grant token here';  
  
$result = $KmsClient->retireGrant([  
    'GrantToken' => $grantToken,  
]);
```

## Node.js

For details, see the [retireGrant](#) property in the [AWS SDK for JavaScript in Node.js](#).

```
// Retire a grant  
//  
const GrantToken = 'Place your grant token here';  
kmsClient.retireGrant({ GrantToken }, (err, data) => {  
    ...  
});
```

# Revoking a Grant

To revoke a grant to an AWS KMS customer master key, use the [RevokeGrant](#) operation. You can revoke a grant to explicitly deny operations that depend on it.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

## Java

For details, see the [revokeGrant](#) method in the [AWS SDK for Java API Reference](#).

```
// Revoke a grant on a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
String grantId = "grant1";  
  
RevokeGrantRequest req = new  
    RevokeGrantRequest().withKeyId(keyId).withGrantId(grantId);
```

```
kmsClient.RevokeGrant(req);
```

## C#

For details, see the [RevokeGrant method](#) in the *AWS SDK for .NET*.

```
// Revoke a grant on a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";
String grantId = "grant1";

RevokeGrantRequest revokeGrantRequest = new RevokeGrantRequest()
{
    KeyId = keyId,
    GrantId = grantId
};
kmsClient.RevokeGrant(revokeGrantRequest);
```

## Python

For details, see the [revoke\\_grant method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Revoke a grant on a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
grant_id = 'grant1'

response = kms_client.revoke_grant(
    KeyId=key_id,
    GrantId=grant_id
)
```

## Ruby

For details, see the [revoke\\_grant](#) instance method in the *AWS SDK for Ruby*.

```
# Revoke a grant on a CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
grantId = 'grant1'

response = kmsClient.revoke_grant({
  key_id: keyId,
  grant_id: grantId
})
```

## PHP

For details, see the [RevokeGrant method](#) in the *AWS SDK for PHP*.

```
// Revoke a grant on a CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
$grantId = "grant1";

$result = $KmsClient->revokeGrant([
```

```
'KeyId' => $keyId,  
'GrantId' => $grantId,  
]);
```

#### Node.js

For details, see the [revokeGrant property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Revoke a grant on a CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const KeyId = 'arn:aws:kms:us-  
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
const GrantId = 'grant1';  
kmsClient.revokeGrant({ GrantId, KeyId }, (err, data) => {  
  ...  
});
```

## Working with Aliases

The examples in this topic use the AWS KMS API to create, view, update, and delete aliases.

An *alias* is an optional display name for a [customer master key \(CMK\)](#) (p. 2). Each CMK can have multiple aliases, but each alias points to only one CMK. The alias name must be unique in the AWS account and region. To simplify code that runs in multiple regions, you can use the same alias name but point it to a different CMK in each region.

You can use AWS KMS API operations to list, create, and delete aliases. You can also update an alias, which associates an existing alias with a different CMK. There is no operation to edit or change an alias name. If you create an alias for a CMK that already has an alias, the operation creates another alias for the same CMK. To change an alias name, delete the current alias and then create a new alias for the CMK.

Because an alias is not a property of a CMK, it can be associated with and disassociated from an existing CMK without changing the properties of the CMK. Deleting an alias does not delete the underlying CMK.

You can use an alias as the value of the `KeyId` parameter only in the following operations:

- `DescribeKey`
- `Encrypt`
- `GenerateDataKey`
- `GenerateDataKeyWithoutPlaintext`
- `ReEncrypt`

Aliases are created in an AWS account and are known only to the account in which you create them. You cannot use an alias name or alias ARN to identify a CMK in a different AWS account.

To specify an alias, use the alias name or alias ARN, as shown in the following example. In either case, be sure to prepend "alias/" to the alias name.

```
// Fully specified ARN  
arn:aws:kms:us-west-2:111122223333:alias/ExampleAlias
```

#### Topics

- [Creating an Alias \(p. 345\)](#)

- [Listing Aliases \(p. 346\)](#)
- [Updating an Alias \(p. 349\)](#)
- [Deleting an Alias \(p. 351\)](#)

## Creating an Alias

To create an alias, use the [CreateAlias](#) operation. The alias must be unique in the account and region. If you create an alias for a CMK that already has an alias, [CreateAlias](#) creates another alias to the same CMK. It does not replace the existing alias.

You cannot create an alias that begins with `aws/`. The `aws/` prefix is reserved by Amazon Web Services for [AWS managed CMKs \(p. 2\)](#).

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

### Java

For details, see the [createAlias method](#) in the *AWS SDK for Java API Reference*.

```
// Create an alias for a CMK
//
String aliasName = "alias/projectKey1";
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String targetKeyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

CreateAliasRequest req = new
    CreateAliasRequest().withAliasName(aliasName).withTargetKeyId(targetKeyId);
kmsClient.createAlias(req);
```

### C#

For details, see the [CreateAlias method](#) in the *AWS SDK for .NET*.

```
// Create an alias for a CMK
//
String aliasName = "alias/projectKey1";
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String targetKeyId = "arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";

CreateAliasRequest createAliasRequest = new CreateAliasRequest()
{
    AliasName = aliasName,
    TargetKeyId = targetKeyId
};
kmsClient.CreateAlias(createAliasRequest);
```

### Python

For details, see the [create\\_alias method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Create an alias for a CMK

alias_name = 'alias/projectKey1'
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
target_key_id = 'arn:aws:kms:us-
west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'
```

```
response = kms_client.create_alias(  
    AliasName=alias_name,  
    TargetKeyId=key_id  
)
```

## Ruby

For details, see the [create\\_alias](#) instance method in the [AWS SDK for Ruby](#).

```
# Create an alias for a CMK  
  
aliasName = 'alias/projectKey1'  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
targetKeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
response = kmsClient.create_alias({  
    alias_name: aliasName,  
    target_key_id: targetKeyId  
})
```

## PHP

For details, see the [CreateAlias method](#) in the [AWS SDK for PHP](#).

```
// Create an alias for a CMK  
//  
$aliasName = "alias/projectKey1";  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
  
$result = $KmsClient->createAlias([  
    'AliasName' => $aliasName,  
    'TargetKeyId' => $keyId,  
]);
```

## Node.js

For details, see the [createAlias property](#) in the [AWS SDK for JavaScript in Node.js](#).

```
// Create an alias for a CMK  
//  
const AliasName = 'alias/projectKey1';  
  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
const TargetKeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';  
kmsClient.createAlias({ AliasName, TargetKeyId }, (err, data) => {  
    ...  
});
```

# Listing Aliases

To list aliases in the account and region, use the [ListAliases](#) operation.

By default, the **ListAliases** command returns all aliases in the account and region. This includes aliases that you created and associated with your [customer managed CMKs](#) (p. 2), and aliases that AWS created and associated with your [AWS managed CMKs](#) (p. 2). The response might also include aliases that have

no `TargetKeyId` field. These are predefined aliases that AWS has created but has not yet associated with a CMK.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details about the Java implementation, see the [listAliases method](#) in the *AWS SDK for Java API Reference*.

```
// List the aliases in this AWS account
//
Integer limit = 10;

ListAliasesRequest req = new ListAliasesRequest().withLimit(limit);
ListAliasesResult result = kmsClient.listAliases(req);
```

#### C#

For details, see the [ListAliases method](#) in the *AWS SDK for .NET*.

```
// List the aliases in this AWS account
//
int limit = 10;

ListAliasesRequest listAliasesRequest = new ListAliasesRequest()
{
    Limit = limit
};
ListAliasesResponse listAliasesResponse = kmsClient.ListAliases(listAliasesRequest);
```

#### Python

For details, see the [list\\_aliases method](#) in the AWS SDK for Python (Boto 3).

```
# List the aliases in this AWS account

response = kms_client.list_aliases(
    Limit=10
)
```

#### Ruby

For details, see the [list\\_aliases](#) instance method in the *AWS SDK for Ruby*.

```
# List the aliases in this AWS account

response = kmsClient.list_aliases({
  limit: 10
})
```

#### PHP

For details, see the [List Aliases method](#) in the *AWS SDK for PHP*.

```
// List the aliases in this AWS account
//
$limit = 10;

$result = $KmsClient->listAliases([
```

```
    'Limit' => $limit,  
  ]);
```

### Node.js

For details, see the [listAliases property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// List the aliases in this AWS account  
//  
const Limit = 10;  
kmsClient.listAliases({ Limit }, (err, data) => {  
    ...  
});
```

To list only the aliases that are associated with a particular CMK, use the `KeyId` parameter. Its value can be the ID or Amazon Resource Name (ARN) of any CMK in the region. You cannot specify an alias name or alias ARN.

### Java

For details about the Java implementation, see the [listAliases method](#) in the *AWS SDK for Java API Reference*.

```
// List the aliases for one CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
ListAliasesRequest req = new ListAliasesRequest().withKeyId(keyId);  
ListAliasesResult result = kmsClient.listAliases(req);
```

### C#

For details, see the [ListAliases method](#) in the *AWS SDK for .NET*.

```
// List the aliases for one CMK  
//  
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
String keyId = "arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab";  
  
ListAliasesRequest listAliasesRequest = new ListAliasesRequest()  
{  
    KeyId = keyId  
};  
ListAliasesResponse listAliasesResponse = kmsClient.ListAliases(listAliasesRequest);
```

### Python

For details, see the [list\\_aliases method](#) in the *AWS SDK for Python (Boto 3)*.

```
# List the aliases for one CMK  
  
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN  
key_id = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'  
  
response = kms_client.list_aliases(  
    KeyId=key_id
```

```
)
```

## Ruby

For details, see the [list\\_aliases](#) instance method in the [AWS SDK for Ruby](#).

```
# List the aliases for one CMK

# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab'

response = kmsClient.list_aliases({
  key_id: keyId
})
```

## PHP

For details, see the [List Aliases method](#) in the *AWS SDK for PHP*.

```
// List the aliases for one CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';

$result = $KmsClient->listAliases([
    'KeyId' => $keyId,
]);
```

## Node.js

For details, see the [listAliases property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// List the aliases for one CMK
//
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const KeyId = 'arn:aws:kms:us-west-2:111122223333:key/1234abcd-12ab-34cd-56ef-1234567890ab';
kmsClient.listAliases({ KeyId }, (err, data) => {
    ...
});
```

# Updating an Alias

To associate an existing alias with a different CMK, use the [UpdateAlias](#) operation.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

## Java

For details about the Java implementation, see the [updateAlias method](#) in the *AWS SDK for Java API Reference*.

```
// Updating an alias
//
String aliasName = "alias/projectKey1";
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String targetKeyId = "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321";
```

```
UpdateAliasRequest req = new UpdateAliasRequest()
    .withAliasName(aliasName)
    .withTargetKeyId(targetKeyId);

kmsClient.updateAlias(req);
```

## C#

For details, see the [UpdateAlias method](#) in the *AWS SDK for .NET*.

```
// Updating an alias
//
String aliasName = "alias/projectKey1";
// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
String targetKeyId = "arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321";

UpdateAliasRequest updateAliasRequest = new UpdateAliasRequest()
{
    AliasName = aliasName,
    TargetKeyId = targetKeyId
};

kmsClient.UpdateAlias(updateAliasRequest);
```

## Python

For details, see the [update\\_alias method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Updating an alias

alias_name = 'alias/projectKey1'
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
key_id = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'

response = kms_client.update_alias(
    AliasName=alias_name,
    TargetKeyId=key_id
)
```

## Ruby

For details, see the [update\\_alias](#) instance method in the *AWS SDK for Ruby*.

```
# Updating an alias

aliasName = 'alias/projectKey1'
# Replace the following fictitious CMK ARN with a valid CMK ID or ARN
keyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321'

response = kmsClient.update_alias({
  alias_name: aliasName,
  target_key_id: keyId
})
```

## PHP

For details, see the [UpdateAlias method](#) in the *AWS SDK for PHP*.

```
// Updating an alias
//
```

```
$aliasName = "alias/projectKey1";

// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
$keyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321';

$result = $KmsClient->updateAlias([
    'AliasName' => $aliasName,
    'TargetKeyId' => $keyId,
]);
```

#### Node.js

For details, see the [updateAlias property](#) in the *AWS SDK for JavaScript in Node.js*.

```
// Updating an alias
//
const AliasName = 'alias/projectKey1';

// Replace the following fictitious CMK ARN with a valid CMK ID or ARN
const TargetKeyId = 'arn:aws:kms:us-west-2:111122223333:key/0987dcba-09fe-87dc-65ba-ab0987654321';
kmsClient.updateAlias({ AliasName, TargetKeyId }, (err, data) => {
    ...
});
```

## Deleting an Alias

To delete an alias, use the [DeleteAlias](#) operation. Deleting an alias has no effect on the underlying CMK.

This example uses the AWS KMS client object that you created in [Creating a Client \(p. 314\)](#).

#### Java

For details, see the [deleteAlias method](#) in the *AWS SDK for Java API Reference*.

```
// Delete an alias for a CMK
//
String aliasName = "alias/projectKey1";

DeleteAliasRequest req = new DeleteAliasRequest().withAliasName(aliasName);
kmsClient.deleteAlias(req);
```

#### C#

For details, see the [DeleteAlias method](#) in the *AWS SDK for .NET*.

```
// Delete an alias for a CMK
//
String aliasName = "alias/projectKey1";

DeleteAliasRequest deleteAliasRequest = new DeleteAliasRequest()
{
    AliasName = aliasName
};
kmsClient.DeleteAlias(deleteAliasRequest);
```

#### Python

For details, see the [delete\\_alias method](#) in the *AWS SDK for Python (Boto 3)*.

```
# Delete an alias for a CMK

alias_name = 'alias/projectKey1'

response = kms_client.delete_alias(
    AliasName=alias_name
)
```

## Ruby

For details, see the [delete\\_alias](#) instance method in the [AWS SDK for Ruby](#).

```
# Delete an alias for a CMK

aliasName = 'alias/projectKey1'

response = kmsClient.delete_alias({
  alias_name: aliasName
})
```

## PHP

For details, see the [DeleteAlias](#) method in the *AWS SDK for PHP*.

```
// Delete an alias for a CMK
//
$aliasName = "alias/projectKey1";

$result = $KmsClient->deleteAlias([
    'AliasName' => $aliasName,
]);
```

## Node.js

For details, see the [deleteAlias](#) property in the *AWS SDK for JavaScript in Node.js*.

```
// Delete an alias for a CMK
//
const AliasName = 'alias/projectKey1';
kmsClient.deleteAlias({ AliasName }, (err, data) => {
    ...
});
```

# Quotas

To make AWS KMS responsive and performant for all users, AWS KMS applies two types of quotas. Each quota is calculated independently for each Region of each AWS account.

## Important

If you need to exceed a quota, you can request a quota increase in Service Quotas. Use the [Service Quotas console](#) or the [RequestServiceQuotaIncrease](#) operation. For details, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*. If Service Quotas for AWS KMS are not available in the AWS Region, please visit the [AWS Support Center](#) and create a case.

- [Resource quotas \(p. 353\)](#): Limit the number of each type of AWS KMS resource.
- [Request quotas \(p. 355\)](#): Limit the number of requests for AWS KMS API operations in a specified interval.

## Resource Quotas

AWS KMS establishes resource quotas to ensure that it can provide fast and resilient service to all of our customers. Some resource quotas apply only to resources that you create, but not to resources that AWS services create for you. Resources that you use, but that aren't in your AWS account, such as [AWS owned CMKs \(p. 4\)](#), do not count against these quotas.

If you have reached a resource limit, requests to create an additional resource of that type generate an `LimitExceededException` error message.

The following table lists and describes the AWS KMS resource quotas in each AWS account and Region. If you need to exceed a quota, you can request a quota increase in Service Quotas. Use the [Service Quotas console](#) or the [RequestServiceQuotaIncrease](#) operation. For details, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*. If Service Quotas for AWS KMS are not available in the AWS Region, please visit the [AWS Support Center](#) and create a case.

Resource	Default Limit	Applies To
<a href="#">Customer Master Keys (CMKs) (p. 354)</a>	10,000	Customer managed CMKs
<a href="#">Aliases (p. 354)</a>	10,000	Customer created aliases
<a href="#">Grants per CMK (p. 354)</a>	10,000	Customer managed CMKs
<a href="#">Grants for a given principal per CMK (p. 354)</a>	500	Customer managed CMKs AWS managed CMKs
<a href="#">Key policy document size (p. 355)</a>	32 KB (32,768 bytes)	Customer managed CMKs AWS managed CMKs

In addition to resource quotas, AWS KMS uses request quotas to ensure the responsiveness of the service. For details, see [the section called "Request Quotas" \(p. 355\)](#).

## Customer Master Keys (CMKs): 10,000

You can have up to 10,000 [customer managed CMKs \(p. 3\)](#) in each Region of your AWS account. This quota applies to all symmetric and asymmetric customer managed CMKs regardless of their [key state \(p. 223\)](#). Each CMK — whether symmetric or asymmetric — is considered to be one resource. [AWS managed CMKs \(p. 4\)](#) and [AWS owned CMKs \(p. 4\)](#) do not count against this quota.

If you need to exceed this quota, request a quota increase in Service Quotas. However, managing a large number of CMKs from the AWS Management Console may be slower than acceptable. If you have a large number of CMKs in an AWS Region, manage them programmatically with the [AWS SDKs](#) or [AWS Command Line Tools](#).

## Aliases: 10,000

You can create up to 10,000 aliases in each Region of your account. Aliases that AWS creates in your account, such as `aws/<service-name>`, do not count against this quota.

An *alias* is a display name that you can map to a CMK. Each alias is mapped to exactly one CMK and multiple aliases can map to the same CMK.

If you increase your CMK resource quota, you might also need to increase your aliases resource quota. For help with requesting a quota increase, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*.

## Grants per CMK: 10,000

Each [customer managed CMK \(p. 3\)](#) can have up to 10,000 grants, including the grants created by [AWS services that are integrated with AWS KMS](#). This quota does not apply to [AWS managed CMKs \(p. 4\)](#) or [AWS owned CMKs \(p. 4\)](#).

One effect of this quota is that you cannot perform more than 10,000 grant-authorized operations that use the same CMK at the same time. After you reach the quota, you can create new grants on the CMK only when an active grant is retired or revoked.

For example, when you attach an Amazon Elastic Block Store (Amazon EBS) volume to an Amazon Elastic Compute Cloud (Amazon EC2) instance, the volume is decrypted so you can read it. To get permission to decrypt the data, Amazon EBS creates a grant for each volume. However, you cannot have more than 10,000 grants on each CMK. Therefore, if all of your Amazon EBS volumes use the same CMK, you cannot attach more than 10,000 volumes at one time.

[Grants \(p. 115\)](#) are an alternative to [key policy \(p. 50\)](#). Like a key policy, a grant is attached to a CMK. You (or an AWS service integrated with AWS KMS) can use a grant to allow a principal to use or manage the CMK. Each grant includes the principal who receives permission to use the CMK, the ID of the CMK, and a list of operations that the grantee can perform.

## Grants for a Given Principal per CMK: 500

You cannot have more than 500 grants on a CMK that specify the same grantee principal. This quota is calculated separately for each CMK in the account. It applies to [customer managed CMKs \(p. 3\)](#) and [AWS managed CMKs \(p. 4\)](#), but not to [AWS owned CMKs \(p. 4\)](#).

For example, when you attach an Amazon Elastic Block Store (Amazon EBS) volume to an Amazon Elastic Compute Cloud (Amazon EC2) instance, the volume is decrypted so you can read it. To get permission to decrypt the data, Amazon EBS creates a grant for each volume. Each grant is unique, but all of the grants have the same grantee principal, a user that assumes a role associated with Amazon EC2 instances. However, you cannot have more than 500 grants for the same principal on each CMK. Therefore, if all of your Amazon EBS volumes use the same CMK, you cannot attach more than 500 volumes at one time.

## Key Policy Document Size: 32 KB

The maximum length of each key policy document is 32 KB (32,768 bytes). If you use a larger policy document to create or update the key policy for a CMK, the operation fails.

If you must exceed this quota, request a quota increase in Service Quotas. For details, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*.

A [key policy document](#) (p. 50) is a collection of policy statements in JSON format. The statements in the key policy document determine who has permission to use the CMK and how they can use it. You may also use IAM policies and grants to control access to the CMK, but every CMK must have a key policy document.

You use a key policy document whenever you create or change a key policy by using the [default view](#) (p. 65) or [policy view](#) (p. 65) in the AWS Management Console, or the [PutKeyPolicy](#) operation. This quota applies to your key policy document, even if you use the [default view](#) (p. 65) in the AWS KMS console, where you don't edit the JSON statements directly.

## Request Quotas

AWS KMS establishes quotas for the number of API operations requested in each second. For a table that lists the per-second request quota for each API operation, see [Request Quotas for Each AWS KMS API Operation](#) (p. 357).

When you exceed an API request quota, AWS KMS *throttles* the request, that is, it rejects an otherwise valid request and returns a `ThrottlingException` error like the following one. To respond, use a [backoff and retry strategy](#).

You have exceeded the rate at which you may call KMS. Reduce the frequency of your calls.  
(Service: AWSKMS; Status Code: 400; Error Code: ThrottlingException; Request ID: `<ID>`)

The request quotas differ with the API operation, the AWS Region, and other factors, such as the CMK type.

### Note

If you need to exceed a quota, you can request a quota increase in Service Quotas. Use the [Service Quotas console](#) or the [RequestServiceQuotaIncrease](#) operation. For details, see [Requesting a Quota Increase](#) in the *Service Quotas User Guide*. If Service Quotas for AWS KMS are not available in the AWS Region, please visit the [AWS Support Center](#) and create a case. If you are exceeding the request quota for the [GenerateDataKey](#) operation, consider using the [data key caching](#) feature of the AWS Encryption SDK. Reusing data keys might reduce the frequency of your requests to AWS KMS.

In addition to request quotas, AWS KMS uses resource quotas to ensure capacity for all users. For details, see [Resource Quotas](#) (p. 353).

### Topics

- [Applying Request Quotas](#) (p. 356)
- [Shared Quotas for Cryptographic Operations](#) (p. 356)
- [API Requests Made on Your Behalf](#) (p. 356)
- [Cross-Account Requests](#) (p. 357)
- [Custom Key Store Quotas](#) (p. 357)
- [Request Quotas for Each AWS KMS API Operation](#) (p. 357)

## Applying Request Quotas

When reviewing request quotas, keep in mind the following information.

- Request quotas apply to both [customer managed CMKs \(p. 3\)](#) and [AWS managed CMKs \(p. 4\)](#). The use of [AWS owned CMKs \(p. 4\)](#) does not count against request quotas for your AWS account, even when they are used to protect resources in your account.
- Throttling is based on all requests on CMKs of all types in the Region. This total includes requests from all principals in the AWS account, including requests from AWS services on your behalf.
- Each request quota is calculated independently. For example, requests for the [CreateKey](#) operation have no effect on the request quota for the [CreateAlias](#) operation. If your [CreateAlias](#) requests are throttled, your [CreateKey](#) requests can still complete successfully.
- Although cryptographic operations share a quota, the shared quota is calculated independently of quotas for other operations. For example, calls to the [Encrypt](#) and [Decrypt](#) operations share a request quota, but that quota is independent of the quota for management operations, such as [EnableKey](#). For example, in the Europe (London) Region, you can perform 10,000 cryptographic operations on symmetric CMKs *plus* 5 [EnableKey](#) operations per second without being throttled.

## Shared Quotas for Cryptographic Operations

AWS KMS cryptographic operations share request quotas. These quotas are displayed in the first row of the [Request quotas table \(p. 357\)](#). The quotas for different types of CMKs are calculated independently. Each quota applies to all requests for these operations in the AWS account and Region with the given key type in each one-second interval.

For example, you might be using [symmetric CMKs \(p. 130\)](#) in an AWS Region with a shared quota of 10,000 requests per second. When you make 7,000 [GenerateDataKey](#) requests per second and 2,000 [Decrypt](#) requests per second, AWS KMS doesn't throttle your requests. However, when you make 9,500 [GenerateDataKey](#) requests and 1,000 [Encrypt](#) requests per second, AWS KMS throttles your requests because they exceed the shared quota.

Similarly, if you are using [asymmetric CMKs \(p. 130\)](#), you can request any combination of the cryptographic operations that are supported by the CMK, just so the total number of cryptographic operations doesn't exceed the request quota for that type of CMK. For example, you can make 300 [Encrypt](#) requests and 200 [Decrypt](#) requests on your RSA-based encryption CMKs without being throttled.

### Note

Asymmetric CMKs and asymmetric data key pairs are supported by AWS KMS only in the following AWS Regions: US East (N. Virginia), US West (Oregon), Asia Pacific (Sydney), Asia Pacific (Tokyo), and Europe (Ireland).

The quotas for different key types are also calculated independently. For example, in the Asia Pacific (Singapore) Region, if you use both symmetric and asymmetric CMKs, you can make up to 10,000 calls per second with symmetric CMKs *plus* up to 500 additional calls per second with your RSA-based asymmetric CMKs, *plus* up to 300 additional requests per second with your ECC-based CMKs.

## API Requests Made on Your Behalf

You can make API requests directly or by using an integrated AWS service that makes API requests to AWS KMS on your behalf. The quota applies to both kinds of requests.

For example, you might store data in Amazon S3 using server-side encryption with AWS KMS (SSE-KMS). Each time you upload or download an S3 object that's encrypted with SSE-KMS, Amazon S3 makes a `GenerateDataKey` (for uploads) or `Decrypt` (for downloads) request to AWS KMS on your behalf. These requests count toward your quota, so AWS KMS throttles the requests if you exceed a combined total of 5,500 (or 10,000 or 30,000 depending upon your AWS Region) uploads or downloads per second of S3 objects encrypted with SSE-KMS.

## Cross-Account Requests

When an application in one AWS account uses a CMK owned by a different account, it's known as a *cross-account request*. For cross-account requests, AWS KMS throttles the account that makes the requests, not the account that owns the CMK. For example, if an application in account A uses a CMK in account B, the CMK use applies only to the quotas in account A.

## Custom Key Store Quotas

Cryptographic operations that use CMKs in a [custom key store](#) (p. 172) share a request quota of 1,800 operations per second for each custom key store. However, not all operations use the quota equally. The `GenerateDataKey`, `GenerateDataKeyWithoutPlaintext`, and `GenerateRandom` operations use approximately three times as much of the per-second quota as the `Encrypt`, `Decrypt`, and `ReEncrypt` operations.

For example, if you are requesting only `Encrypt` and `Decrypt` operations, you can perform approximately 1,800 operations per second. If, instead, you request repeated `GenerateDataKey` operations, your performance might be closer to 600 operations per second. For applications patterns that consist of roughly equal numbers of `GenerateDataKey` and `Decrypt` operations, you can expect about 1,200 operations per second.

Unlike other AWS KMS quotas, you cannot raise the custom key store quota by using Service Quotas or by creating a case in AWS Support.

### Note

If the AWS CloudHSM cluster that is associated with the custom key store is processing numerous commands, including those unrelated to the custom key store, you might get an `AWS KMS ThrottlingException` at a lower-than-expected rate. If this occurs, lower your request rate to AWS KMS, reduce the unrelated load, or use a dedicated AWS CloudHSM cluster for your custom key store.

## Request Quotas for Each AWS KMS API Operation

API Operation	Request Quotas (per second)
<code>Decrypt</code> <code>Encrypt</code>	These shared quotas vary with the AWS Region and the type of CMK used in the request. Each quota is calculated separately.
<code>GenerateDataKey</code> (symmetric)	
<code>GenerateDataKeyWithoutPlaintext</code> (symmetric)	Symmetric CMK quota: <ul style="list-style-type: none"><li>• 5,500 (shared)</li><li>• 10,000 (shared) in the following Regions:<ul style="list-style-type: none"><li>• US East (Ohio), us-east-2</li><li>• Asia Pacific (Singapore), ap-southeast-1</li><li>• Asia Pacific (Sydney), ap-southeast-2</li><li>• Asia Pacific (Tokyo), ap-northeast-1</li><li>• Europe (Frankfurt), eu-central-1</li></ul></li></ul>
<code>GenerateRandom</code>	
<code>ReEncrypt</code>	
<code>Sign</code> (asymmetric)	

API Operation	Request Quotas (per second)
Verify (asymmetric)	<ul style="list-style-type: none"> <li>Europe (London), eu-west-2</li> <li>30,000 (shared) in the following Regions: <ul style="list-style-type: none"> <li>US East (N. **Current API version:** 2014-11-01

update-history-change	update-history-description	update-history-date
<a href="#">New feature</a>	Added support for asymmetric customer master keys and asymmetric data keys.	November 25, 2019
<a href="#">Updated feature</a>	You can view the key policy of AWS managed CMKs in the AWS KMS console. This feature used to be limited to customer managed CMKs.	November 15, 2019
<a href="#">New feature</a>	Explains how to use <a href="#">hybrid post-quantum key exchange</a> algorithms in TLS for your calls to AWS KMS.	November 4, 2019
<a href="#">Quota change</a>	Increased the resource quotas for some APIs that manage CMKs.	September 18, 2019
<a href="#">Quota change</a>	Changed the resource quotas for customer master keys (CMKs), aliases, and grants per CMK.	March 27, 2019
<a href="#">Quota change</a>	Changed the shared per-second request quota for cryptographic operations that use customer master keys (CMKs) in a custom key store.	March 7, 2019
<a href="#">New feature</a>	Explains how to create and manage AWS KMS <a href="#">custom key stores</a> . Each key store is backed by an AWS CloudHSM cluster that you own and control.	November 26, 2018

<a href="#">New console</a>	Explains how to use the new AWS KMS console, which is independent of the IAM console. The original console, and instructions for using it, will remain available for a brief period to give you time to familiarize yourself with the new console.	November 7, 2018
<a href="#">Quota change</a>	Changed the shared <a href="#">request quota</a> for use of customer master keys.	August 21, 2018
<a href="#">New content</a>	Explains <a href="#">how AWS Secrets Manager uses AWS KMS</a> customer master keys to encrypt the secret value in a secret.	July 13, 2018
<a href="#">New content</a>	Explains <a href="#">how DynamoDB uses AWS KMS</a> customer master keys to support its server-side encryption option.	May 23, 2018
<a href="#">New feature</a>	Explains how to <a href="#">use a private endpoint in your VPC</a> to connect directly to AWS KMS, instead of connecting over the internet.	January 22, 2018

## Earlier Updates

The following table describes the important changes to the AWS Key Management Service Developer Guide prior to 2018.

Change	Description	Date
New content	Added documentation about <a href="#">Tagging Keys</a> (p. 39).	February 15, 2017
New content	Added documentation about <a href="#">Monitoring Customer Master Keys</a> (p. 286) and <a href="#">Monitoring with Amazon CloudWatch</a> (p. 287).	August 31, 2016
New content	Added documentation about <a href="#">Importing Key Material</a> (p. 147).	August 11, 2016
New content	Added the following documentation: <a href="#">Overview of Managing Access</a> (p. 47), <a href="#">Using IAM Policies</a> (p. 67), <a href="#">AWS KMS API Permissions Reference</a> (p. 76), and <a href="#">Using Policy Conditions</a> (p. 86).	July 5, 2016

Change	Description	Date
Update	Updated portions of the documentation in the <a href="#">Authentication and Access Control (p. 46)</a> chapter.	July 5, 2016
Update	Updated the <a href="#">Quotas (p. 353)</a> page to reflect new default quotas.	May 31, 2016
Update	Updated the <a href="#">Quotas (p. 353)</a> page to reflect new default quotas, and updated the <a href="#">Grant Tokens (p. 16)</a> documentation to improve clarity and accuracy.	April 11, 2016
New content	Added documentation about <a href="#">Allowing Multiple IAM Users to Access a CMK (p. 66)</a> and <a href="#">Using the IP Address Condition (p. 87)</a> .	February 17, 2016
Update	Updated the <a href="#">Using Key Policies in AWS KMS (p. 50)</a> and <a href="#">Changing a Key Policy (p. 64)</a> pages to improve clarity and accuracy.	February 17, 2016
Update	Updated the <a href="#">Getting Started (p. 17)</a> topic pages to improve clarity.	January 5, 2016
New content	Added documentation about <a href="#">How AWS CloudTrail Uses AWS KMS (p. 228)</a> .	November 18, 2015
New content	Added instructions for <a href="#">Changing a Key Policy (p. 64)</a> .	November 18, 2015
Update	Updated the documentation about <a href="#">How Amazon Relational Database Service (Amazon RDS) Uses AWS KMS (p. 254)</a> .	November 18, 2015
New content	Added documentation about <a href="#">How Amazon WorkSpaces Uses AWS KMS (p. 282)</a> .	November 6, 2015
Update	Updated the <a href="#">Using Key Policies in AWS KMS (p. 50)</a> page to improve clarity.	October 22, 2015

Change	Description	Date
New content	Added documentation about <a href="#">Deleting Customer Master Keys</a> (p. 160), including supporting documentation about <a href="#">Creating an Amazon CloudWatch Alarm</a> (p. 165) and <a href="#">Determining Past Usage of a Customer Master Key</a> (p. 169).	October 15, 2015
New content	Added documentation about <a href="#">Determining Access to an AWS KMS Customer Master Key</a> (p. 118).	October 15, 2015
New content	Added documentation about <a href="#">How Key State Affects Use of a Customer Master Key</a> (p. 223).	October 15, 2015
New content	Added documentation about <a href="#">How Amazon Simple Email Service (Amazon SES) Uses AWS KMS</a> (p. 262).	October 1, 2015
Update	Updated the <a href="#">Quotas</a> (p. 353) page to explain the new request quotas.	August 31, 2015
New content	Added information about the charges for using AWS KMS. See <a href="#">AWS KMS Pricing</a> (p. 2).	August 14, 2015
New content	Added request quotas to the AWS KMS <a href="#">Quotas</a> (p. 353).	June 11, 2015
New content	Added a new Java code sample demonstrating use of the <a href="#">UpdateAlias</a> operation. See <a href="#">Updating an Alias</a> (p. 349).	June 1, 2015
Update	Moved the <a href="#">AWS Key Management Service regions table</a> to the <i>AWS General Reference</i> .	May 29, 2015
New content	Added documentation about <a href="#">How Amazon EMR Uses AWS KMS</a> (p. 249).	January 28, 2015
New content	Added documentation about <a href="#">How Amazon WorkMail Uses AWS KMS</a> (p. 276).	January 28, 2015
New content	Added documentation about <a href="#">How Amazon Relational Database Service (Amazon RDS) Uses AWS KMS</a> (p. 254).	January 6, 2015

Change	Description	Date
New content	Added documentation about <a href="#">How Amazon Elastic Transcoder Uses AWS KMS (p. 245)</a> .	November 24, 2014
New guide	Introduced the <i>AWS Key Management Service Developer Guide</i> .	November 12, 2014
